Babel

Version 3.9n 2016/01/05

*Original author*Johannes L. Braams

Current maintainer Javier Bezos The standard distribution of LATEX contains a number of document classes that are meant to be used, but also serve as examples for other users to create their own document classes. These document classes have become very popular among LATEX users. But it should be kept in mind that they were designed for American tastes and typography. At one time they even contained a number of hard-wired texts.

This manual describes babel, a package that makes use of the capabilities of TEX version 3 and, to some extent, xetex and luatex, to provide an environment in which documents can be typeset in a language other than US English, or in more than one language or script.

However, no attempt has been done to take full advantage of the features provided by the latter, which would require a completely new core (as for example polyglossia or as part of LATEX3).

Part I

User guide

1 The user interface

The basic user interface of this package is quite simple. It consists of a set of commands that switch from one language to another, and a set of commands that deal with shorthands. It is also possible to find out what the current language is. In most cases, a single language is required, and then all you need in LATEX is to load the package using its standard mechanism for this purpose, namely, passing that language as an optional argument.

In multilingual documents, just use several option. So, in \LaTeX 22e the preamble of the document:

```
\documentclass{article}
\usepackage[dutch,english]{babel}
```

would tell IATEX that the document would be written in two languages, Dutch and English, and that English would be the first language in use, and the main one. You can also set the main language explicitly:

```
\documentclass{article}
\usepackage[main=english,dutch]{babel}
```

Another approach is making dutch and english global options in order to let other packages detect and use them:

```
\documentclass[dutch,english]{article}
\usepackage{babel}
\usepackage{varioref}
```

In this last example, the package varioref will also see the options and will be able to use them.

Languages may be set as global and as package option at the same time, but in such a case you should set explicitly the main language with the package option main:

```
\documentclass[italian]{book}
\usepackage[ngerman,main=italian]{babel}
```

New 3.9c The basic behaviour of some languages can be modified when loading babel by means of *modifiers*. They are set after the language name, and are prefixed with a dot (only when the language is set as package option – neither global options nor the main key accept them). An example is (spaces are not significant and they can be added or removed):¹

```
\usepackage[latin.medieval, spanish.notilde.lcroman, danish]{babel}
```

Attributes (described below) are considered modifiers, ie, you can set an attribute by including it in the list of modifiers. However, modifiers is a more general mechanism.

¹No predefined "axis" for modifiers are provided because languages and their scripts have quite different needs.

Because of the way babel has evolved, "language" can refer to (1) a set of hyphenation patterns as preloaded into the format, (2) a package option, (3) an ldf file, and (4) a name used in the document to select a language or dialect. So, a package option refers to a language in a generic way – sometimes it is the actual language name used to select it, sometimes it is a file name loading a language with a different name, sometimes it is a file name loading several languages. Please, read the documentation for specific languages for further info. Loading directly sty files in LATEX (ie, \usepackage{ $\langle language \rangle$ }) is deprecated and you will get the error:

```
! Package babel Error: You are loading directly a language style.
(babel) This syntax is deprecated and you must use
(babel) \usepackage[language]{babel}.
```

Another typical error when using babel is the following:³

```
! Package babel Error: Unknown language 'LANG'. Either you have misspelled (babel) its name, it has not been installed, or you requested (babel) it in a previous run. Fix its name, install it or just (babel) rerun the file, respectively
```

The most frequent reason is, by far, the latest (for example, you included spanish, but you realized this language is not used after all, and therefore you removed it from the option list). In most cases, the error vanishes when the document is typeset again, but in more severe ones you will need to remove the aux file. In Plain, load languages styles with \input and then use \begindocument (the latter is defined by babel):

```
\input estonian.sty
\begindocument
```

Note not all languages provide a sty file and some of them are not compatible with $\operatorname{Plain.}^4$

1.1 Selecting languages

This section describes the commands to be used in the document to switch the language in multilingual document.

The main language is selected automatically when the document environment begins. In the preamble it has *not* been selected, except hyphenation patterns and the name assigned to \languagename (in particular, shorthands, captions and date are not activated). If you need to define boxes and the like in the preamble, you might want to use some of the following commands.

\selectlanguage

```
\{\langle language \rangle\}
```

When a user wants to switch from one language to another he can do so using the macro \selectlanguage. This macro takes the language, defined previously by a language definition file, as its argument. It calls several macros that should be defined in the language definition files to activate the special definitions for the language chosen. For "historical reasons", a macro name is converted to a

 $^{^{2}}$ In former versions the error read "You have used an old interface to call babel", not very helpful.

³In former versions the error read "You haven't loaded the language LANG yet".

⁴Even in the babel kernel there were some macros not compatible with plain. Hopefully these issues will be fixed soon.

language name without the leading \; in other words, the two following declarations are equivalent:

```
\selectlanguage{german}
\selectlanguage{\german}
```

Using a macro instead of a "real" name is deprecated.

If used inside braces there might be some non-local changes, as this would be roughly equivalent to:

```
{\selectlanguage{<inner-language>} ...}\selectlanguage{<outer-language>}
```

If you want a change which is really local, you must enclose this code with an additional grouping level.

This command can be used as environment, too.

\begin{otherlanguage}

```
{\langle language \rangle} ... \end{otherlanguage}
```

The environment otherlanguage does basically the same as \selectlanguage, except the language change is (mostly) local to the environment.

Actually, there might be some non-local changes, as this environment is roughly equivalent to:

```
\begingroup
\selectlanguage{<inner-language>}
...
\endgroup
\selectlanguage{<outer-language>}
```

If you want a change which is really local, you must enclose this environment with an additional grouping, like braces {}.

Spaces after the environment are ignored.

\foreignlanguage

```
{\langle language \rangle} {\langle text \rangle}
```

The command \foreignlanguage takes two arguments; the second argument is a phrase to be typeset according to the rules of the language named in its first argument. This command (1) only switches the extra definitions and the hyphenation rules for the language, *not* the names and dates, (2) does not send information about the language to auxiliary files (i.e., the surrounding language is still in force), and (3) it works even if the language has not been set as package option (but in such a case it only sets the hyphenation patterns and a warning is shown).

\begin{otherlanguage*}

```
{\langle language \rangle} ... \end{otherlanguage*}
```

Same as \foreignlanguage but as environment. Spaces after the environment are *not* ignored.

This environment (or in some cases otherlanguage) may be required for intermixing left-to-right typesetting with right-to-left typesetting in engines not supporting a change in the writing direction inside a line.

\begin{hyphenrules}

```
{\language\} \ldots \end{hyphenrules}
```

The environment hyphenrules can be used to select *only* the hyphenation rules to be used (it can be used as command, too). This can for instance be used to select

'nohyphenation', provided that in language.dat the 'language' nohyphenation is defined by loading zerohyph.tex. It deactivates language shorthands, too (but not user shorthands).

Except for these simple uses, hyphenrules is discouraged and otherlanguage* (the starred version) is preferred, as the former does not take into account possible changes in encodings or characters like, say, ' done by some languages (eg, italian, frenchb, ukraineb). To set hyphenation exceptions, use \babelhyphenation (see below).

1.2 More on selection

\babeltags

```
\{\langle tag1 \rangle = \langle language1 \rangle, \langle tag2 \rangle = \langle language2 \rangle, \dots \}
```

New 3.9i In multilingual documents with many language switches the commands above can be cumbersome. With this tool shorter names can be defined. It adds nothing really new – it is just syntactical sugar.

It defines $\text{text}\langle tag1\rangle\{\langle text\rangle\}\$ to be $\text{foreignlanguage}\{\langle language1\rangle\}\{\langle text\rangle\}\$, and $\text{begin}\{\langle tag1\rangle\}\$ to be $\text{begin}\{otherlanguage*\}\{\langle language1\rangle\}\$, and so on. Note $\langle tag1\rangle$ is also allowed, but remember set it locally inside a group. So, with

```
\babeltags{de = german}
```

yo can write

```
text \textde{German text} text
```

and

text
\begin{de}
German text
\end{de}
text

\babelensure

[include= $\langle commands \rangle$, exclude= $\langle commands \rangle$, fontenc= $\langle encoding \rangle$] { $\langle language \rangle$ }

New 3.9i Except in a few languages, like Russian, captions and dates are just strings, and do not switch the language. That means you should set it explicitly if you want to use them, or hyphenation (and in some cases the text itself) will be wrong. For example:

```
\foreignlanguage{russian}{text \foreignlanguage{polish}{\seename} text}
```

Of course, T_EX can do it for you. To avoid switching the language all the while, \babelensure redefines the captions for a given language to wrap them with a selector. By default only the basic captions and \today are redefined, but you can add further macros with the key include in the optional argument (without commas). Macros not to be modified are listed in exclude. You can also enforce a font encoding with fontenc.⁵ A couple of examples:

```
\babelensure[include=\Today]{spanish}
\babelensure[fontenc=T5]{vietnamese}
```

 $^{^{5}}$ With it encoded string may not work as expected.

They are activated when the language is selected (at the afterextras event), and it makes some assumptions which could not be fulfilled in some languages. Note also you should include only macros defined by the language, not global macros (eg, \TeX of \dag).

1.3 Getting the current language name

\languagename

The control sequence \languagename contains the name of the current language. However, due to some internal inconsistencies in catcodes it should *not* be used to test its value (use iflang, by Heiko Oberdiek).

\iflanguage

```
{\langle language \rangle} {\langle true \rangle} {\langle false \rangle}
```

If more than one language is used, it might be necessary to know which language is active at a specific time. This can be checked by a call to \iflanguage, but note here "language" is used in the T_EX sense, as a set of hyphenation patterns, and *not* as its babel name. This macro takes three arguments. The first argument is the name of a language; the second and third arguments are the actions to take if the result of the test is true or false respectively. The advice about \languagename also applies here – use iflang instead of \iflanguage if possible.

1.4 Selecting scripts

Currently babel provides no standard interface to select scripts, because they are best selected with either \fontencoding (low level) or a language name (high level). Even the Latin script may require different encodings (ie, sets of glyphs) depending on the language, and therefore such a switch would be in a sense incomplete.⁶

Some languages sharing the same script define macros to switch it (eg, \textcyrillic), but be aware they may also set the language to a certain default. Even the babel core defined \textlatin, but is was somewhat buggy because in some cases it messed up encodings and fonts (for example, if the main latin encoding was LY1), and therefore it has been deprecated.⁷

\ensureascii

 $\{\langle text \rangle\}$

New 3.9i This macro makes sure \(\text\) is typeset with a LICR-savvy encoding in the ASCII range. It is used to redefine \TeX and \LaTeX so that they are correctly typeset even with LGR or X2 (the complete list is stored in \BabelNonASCII, which by default is LGR, X2, OT2, OT3, OT6, LHE, LWN, LMA, LMC, LMS, LMU, but you can modify it). So, in some sense it fixes the bug described in the previous paragraph. If non-ASCII encodings are not loaded (or no encoding at all), it is no-op (also \TeX and \LaTeX are not redefined); otherwise, \ensureascii switches to the encoding at the beginning of the document if ASCII-savvy, or else the last ASCII-savvy encoding loaded. For example, if you load LY1, LGR, then it is set to LY1, but if you load LY1, T2A it is set to T2A. The symbol encodings TS1, T3, and TS3 are not taken into account, since they are not used for "ordinary" text.

⁶The so-called Unicode fonts does not improve the situation either. So, a font suited for Vietnamese is not necessarily suited for, say, romanization of Indic languages, and the fact it contains glyphs for Modern Greek does not mean it includes them for Classic Greek. As to directionality, it poses special challenges because it also affects individual characters and layout elements.

⁷But still defined for backwards compatibility.

The foregoing rules (which are applied "at begin document") cover most of cases. Note no asumption is made on characters above 127, which may not follow the LICR conventions – the goal is just to ensure most of the ASCII letters and symbols are the right ones.

1.5 Shorthands

A shorthand is a sequence of one or two characters that expands to arbitrary $T_{\hbox{\footnotesize E}}X$ code.

Shorthands can be used for different kinds of things, as for example: (1) in some languages shorthands such as "a are defined to be able to hyphenate the word if the encoding is 0T1; (2) in some languages shorthands such as ! are used to insert the right amount of white space; (3) several kinds of discretionaries and breaks can be inserted easily with "-, "=, etc.

The package inputenc as well as xetex an luatex have alleviated entering non-ASCII characters, but minority languages and some kinds of text can still require characters not directly available in the keyboards (and sometimes not even as separated or precomposed Unicode characters). As to the point 2, now pdfTeX provides \knbccode. Tools of point 3 can be still very useful in general. There are three levels of shorthands: user, language, and system (by order of precedence). Version 3.9 introduces the language user level on top of the user level, as described below. In most cases, you will use only shorthands provided by languages.

Please, note the following:

- 1. Activated chars used for two-char shorthands cannot be followed by a closing brace } and the spaces following are gobbled. With one-char shorthands (eg, :), they are preserved.
- 2. If on a certain level (system, language, user) there is a one-char shorthand, two-char ones starting with that char and on the same level are ignored.

A typical error when using shorthands is the following:

```
! Argument of \language@active@arg" has an extra }.
```

It means there is a closing brace just after a shorthand, which is not allowed (eg, "}). Just add {} after (eg, "{}}).

\shorthandon \shorthandoff

```
\{\langle shorthands-list \rangle\}\
*\{\langle shorthands-list \rangle\}
```

It is sometimes necessary to switch a shorthand character off temporarily, because it must be used in an entirely different way. For this purpose, the user commands \shorthandoff and \shorthandon are provided. They each take a list of characters as their arguments.

The command \shorthandoff sets the \catcode for each of the characters in its argument to other (12); the command \shorthandon sets the \catcode to active (13). Both commands only work on 'known' shorthand characters. If a character is not known to be a shorthand character its category code will be left unchanged. New 3.9a Note however, \shorthandoff does not behave as you would expect with characters like \sim or $^$, because they usually are not "other". For them \shorthandoff* is provided, so that with

```
\shorthandoff*{~^}
```

~ is still active, very likely with the meaning of a non-breaking space, and ^ is the superscript character. The catcodes used are those when the shorthands are defined, usually when language files are loaded.

\useshorthands

```
*\{\langle char \rangle\}
```

The command \useshorthands initiates the definition of user-defined shorthand sequences. It has one argument, the character that starts these personal shorthands.

New 3.9a However, user shorthands are not always alive, as they may be deactivated by languages (for example, if you use " for your user shorthands and switch from german to french, they stop working). Therefore, a starred version \useshorthands* $\{\langle char \rangle\}$ is provided, which makes sure shorthands are always activated.

Currently, if the package option shorthands is used, you must include any character to be activated with \useshorthands. This restriction will be lifted in a future release.

\defineshorthand

```
[\langle language \rangle, \langle language \rangle, ...] \{\langle shorthand \rangle\} \{\langle code \rangle\}
```

The command \defineshorthand takes two arguments: the first is a one- or two-character shorthand sequence, and the second is the code the shorthand should expand to.

New 3.9a An optional argument allows to (re)define language and system shorthands (some languages do not activate shorthands, so you may want to add \languageshorthands{ $\langle lang \rangle$ } to the corresponding \extras $\langle lang \rangle$). By default, user shorthands are (re)defined.

User shorthands override language ones, which in turn override system shorthands. Language-dependent user shorthands (new in 3.9) take precedence over "normal" user shorthands.

As an example of their applications, let's assume you want a unified set of shorthand for discretionaries (languages do not define shorthands consistently, and "-, \-, "= have different meanings). You could start with, say:

```
\useshorthands*{"}
\defineshorthand{"*}{\babelhyphen{soft}}
\defineshorthand{"-}{\babelhyphen{hard}}
```

However, behaviour of hyphens is language dependent. For example, in languages like Polish and Portugese, a hard hyphen inside compound words are repeated at the beginning of the next line. You could then set:

```
\defineshorthand[*polish,*portugese]{"-}{\babelhyphen{repeat}}
```

Here, options with * set a language-dependent user shorthand, which means the generic one above only applies for the rest of languages; without * they would (re)define the language shorthands instead, which are overriden by user ones. Now, you have a single unified shorthand ("-), with a content-based meaning ('compound word hyphen') whose visual behavior is that expected in each context.

\aliasshorthand

```
\{\langle original \rangle\}\{\langle alias \rangle\}
```

The command \aliasshorthand can be used to let another character perform the same functions as the default shorthand character. If one prefers for example to use the character / over " in typing Polish texts, this can be achieved by entering

\aliasshorthand{"}{/}. Please note the substitute character must not have been declared before as shorthand (in such case, \aliashorthands is ignored). The following example shows how to replace a shorthand by another

```
\aliasshorthand{~}{^}
\AtBeginDocument{\shorthandoff*{~}}
```

However, shorthands remember somehow the original character, and the fallback value is that of the latter. So, in this example, if no shorthand if found, ^ expands to a non-breaking space, because this is the value of ~ (internally, ^ calls \active@char~ or \normal@char~). Furthermore, if you change the system value of ^ with \defineshorthand nothing happens.

\languageshorthands

```
\{\langle language \rangle\}
```

The command \languageshorthands can be used to switch the shorthands on the language level. It takes one argument, the name of a language or none (the latter does what its name suggests). Note that for this to work the language should have been specified as an option when loading the babel package. For example, you can use in english the shorthands defined by ngerman with

```
\addto\extrasenglish{\languageshorthands{ngerman}}
```

(You may also need to activate them with, for example, \useshorthands.) Very often, this is a more convenient way to deactivate shorthands than \shorthandoff, as for example if you want to define a macro to easy typing phonetic characters with tipa:

\babelshorthand

```
\{\langle shorthand \rangle\}
```

With this command you can use a shorthand even if (1) not activated in shorthands (in this case only shorthands for the current language are taken into account, ie, not user shorthands), (2) turned off with \shorthandoff or (3) deactivated with the internal \bbl@deactivate; for example, \babelshorthand{"u} or \babelshorthand{:}. (You can conveniently define your own macros, or even you own user shorthands provided they do not ovelap.) For your records, here is a list of shorthands, but you must check them, as they may change:

Languages with no shorthands Croatian, English (any variety), Indonesian, Hebrew, Interlingua, Irish, Lower Sorbian, Malaysian, North Sami, Romanian, Scottish, Welsh

Languages with only " as defined shorthand character Albanian, Bulgarian, Danish, Dutch, Finnish, German (old and new orthography, also Austrian), Icelandic, Italian, Norwegian, Polish, Portuguese (also Brazilian), Russian, Serbian (with Latin script), Slovene, Swedish, Ukrainian, Upper Sorbian

```
Basque " ' ~
Breton : ; ? !
Catalan " ' '
```

⁸Actually, any name not corresponding to a language group does the same as none. However, follow this convention because it might be enforced in future releases of babel to catch possible errors.

⁹Thanks to Enrico Gregorio

Czech " Esperanto ^
Estonian " ~
French (all varieties) : ; ? !
Galician " . ' ~ < >
Greek ~
Hungarian '
Kurmanji ^
Latin " ^ =
Slovak " ^ ' Spanish " . < > '
Turkish : ! =

In addition, the babel core declares ~ as a one-char shorthand which is let, like the standard ~, to a non breaking space. 10

1.6 Package options

New 3.9a These package options are processed before language options, so that they are taken into account irrespective of its order. The first three options have been available in previous versions.

KeepShorthandsActive

Tells babel not to deactivate shorthands after loading a language file, so that they are also availabe in the preamble.

activeacute

For some languages babel supports this options to set ' as a shorthand in case it is not done by default.

activegrave

Same for '.

shorthands=

 $\langle char \rangle \langle char \rangle ... \mid off$

The only language shorthands activated are those given, like, eg:

```
\usepackage[esperanto,frenchb,shorthands=:;!?]{babel}
```

If ' is included, activeacute is set; if ' is included, activegrave is set. Active characters (like \sim) should be preceded by \string (otherwise they will be expanded by LATEX before they are passed to the package and therefore they will not be recognized); however, t is provided for the common case of \sim (as well as c for not so common case of the comma).

With shorthands=off no language shorthands are defined, As some languages use this mechanism for tools not available otherwise, a macro \babelshorthand is defined, which allows using them; see above.

safe= none | ref | bib

Some IATEX macros are redefined so that using shorthands is safe. With safe=bib only \nocite, \bibcite and \bibitem are redefined. With safe=ref only \newlabel, \ref and \pageref are redefined (as well as a few macros from varioref and ifthen). With safe=none no macro is redefined. This option is recommended, because a good deal of incompatibilities and errors are related to

¹⁰This declaration serves to nothing, but it is preserved for backward compatibility.

these redefinitions – of course, in such a case you cannot use shorthands in these macros, but this is not a real problem (just use "allowed" characters).

math= active | normal

Shorthands are mainly intended for text, not for math. By setting this option with the value normal they are deactivated in math mode (default is active) and things like \${a'}\$ (a closing brace after a shorthand) are not a source of trouble any more.

config= \langle file \rangle

Load $\langle \mathit{file} \rangle$.cfg instead of the default config file bblopts.cfg (the file is loaded even with noconfigs).

main= ⟨language⟩

Sets the main language, as explained above, ie, this language is always loaded last. If it is not given as package or global option, it is added to the list of requested languages.

headfoot= \language \rangle

By default, headlines and footlines are not touched (only marks), and if they contain language dependent macros (which is not usual) there may be unexpected results. With this option you may set the language in heads and foots.

noconfigs Global and language default config files are not loaded, so you can make sure your document is not spoilt by an unexpected .cfg file. However, if the key config is set, this file is loaded.

showlanguages Prints to the log the list of languages loaded when the format was created: number (remember dialects can share it), name, hyphenation file and exceptions file.

nocase New 3.91 Language settings for uppercase and lowercase mapping (as set by \SetCase) are ignored. Use only if there are incompatibilities with other packages.

silent New 3.91 No warnings and no *infos* are written to the log file. 11

strings= generic | unicode | encoded | \langle label \rangle | \langle font encoding \rangle

Selects the encoding of strings in languages supporting this feature. Predefined labels are generic (for traditional T_EX , LICR and ASCII strings), unicode (for engines like xetex and luatex) and encoded (for special cases requiring mixed encodings). Other allowed values are font encoding codes (T1, T2A, LGR, L7X...), but only in languages supporting them. Be aware with encoded captions are protected, but they work in MakeUppercase and the like.

hyphenmap= off | main | select | other | other*

New 3.9g Sets the behaviour of case mapping for hyphenation, provided the language defines it.¹² It can take the following values:

¹¹You can use alternatively the package silence.

 $^{^{12}}$ Turned off in plain.

off deactivates this feature and no case mapping is applied;

first sets it at the first switching commands in the current or parent scope
 (typically, when the aux file is first read and at \begin{document}, but also
 the first \selectlanguage in the preamble), and it's the default if a single
 language option has been stated;¹³

select sets it only at \selectlanguage;

other also sets it at otherlanguage;

other* also sets it at otherlanguage* as well as in heads and foots (if the option headfoot is used) and in auxiliary files (ie, at \select@language), and it's the default if several language options have been stated. The option first can be regarded as an optimized version of other* for monolingual documents.

1.7 The base option

With this package option babel just loads some basic macros (those in switch.def), defines \AfterBabelLanguage and exits. It also selects the hyphenations patterns for the last language passed as option (by its name in language.dat). There are two main uses: classes and packages, and as a last resort in case there are, for some reason, incompatible languages. It can be used if you just want to select the hyphenations patterns of a single language, too.

\AfterBabelLanguage

```
\{\langle option\text{-}name \rangle\}\{\langle code \rangle\}
```

This command is currently the only provided by base. Executes $\langle code \rangle$ when the file loaded by the corresponding package option is finished (at \ldf@finish). The setting is global. So

```
\AfterBabelLanguage{frenchb}{...}
```

does ... at the end of frenchb.ldf. It can be used in ldf files, too, but in such a case the code is executed only if $\langle option\text{-}name \rangle$ is the same as \CurrentOption (which could not be the same as the option name as set in \usepackage!). For example, consider two languages foo and bar defining the same \macro with \newcommand. An error is raised if you attempt to load both. Here is a way to overcome this problem:

```
\usepackage[base]{babel}
\AfterBabelLanguage{foo}{%
  \let\macroFoo\macro
  \let\macro\relax}
\usepackage[foo,bar]{babel}
```

1.8 Hooks

New 3.9a A hook is a piece of code to be executed at certain events. Some hooks are predefined when luatex and xetex are used.

\AddBabelHook

```
{\langle name \rangle} {\langle event \rangle} {\langle code \rangle}
```

¹³Duplicated options count as several ones.

¹⁴Providing foreign is pointless, because the case mapping applied is that at the end of paragraph, but if either xetex or luatex change this behaviour it might be added. On the other hand, other is provided even if I [JBL] think it isn't really useful, but who knows.

The same name can be applied to several events. Hooks may be enabled and disabled for all defined events with ${\bf EnableBabelHook}\{\langle name \rangle\}$,

\DisableBabelHook{ $\langle name \rangle$ }. Names containing the string babel are reserved (they are used, for example, by \useshortands* to add a hook for the event afterextras).

Current events are the following; in some of them you can use one to three T_EX parameters (#1, #2, #3), with the meaning given:

adddialect (language name, dialect name) Used by luababel.def to load the
 patterns if not preloaded.

patterns (language name, language with encoding) Executed just after the
 \language has been set. The second argument has the patterns name
 actually selected (in the form of either lang: ENC or lang).

hyphenation (language name, language with encoding) Executed locally just before exceptions given in \babelhyphenation are actually set.

defaultcommands Used (locally) in \StartBabelCommands.

encodedcommands (input, font encodings) Used (locally) in \StartBabelCommands.
Both xetex and luatex make sure the encoded text is read correctly.

stopcommands Used to reset the the above, if necessary.

write This event comes just after the switching commands are written to the aux file.

beforeextras Just before executing \extras $\langle language \rangle$. This event and the next one should not contain language-dependent code (for that, add it to \extras $\langle language \rangle$).

afterextras Just after executing $\ensuremath{\mbox{\mbox{\mbox{a}}}}$. For example, the following deactivates shorthands in all languages:

```
\AddBabelHook{noshort}{afterextras}{\languageshorthands{none}}
```

stringprocess Instead of a parameter, you can manipulate the macro
 \BabelString containing the string to be defined with \SetString. For
 example, to use an expanded version of the string in the definition, write:

```
\AddBabelHook{myhook}{stringprocess}{%
  \protected@edef\BabelString{\BabelString}}
```

initiateactive (char as active, char as other, original char) New 3.9i Executed just after a shorthand has been 'initiated'. The three parameters are the same character with different catcodes: active, other (\string'ed) and the original one.

afterreset New 3.9i Executed when selecting a language just after \originalTeX is run and reset to its base value, before executing \captions \language \rangle and \date \language \rangle.

Four events are used in hyphen.cfg, which are handled in a quite different way for efficiency reasons – unlike the precedent ones, they only have a single hook and replace a default definition.

everylanguage (language) Executed before every language patterns are loaded.
loadkernel (file) By default loads switch.def. It can be used to load a different
version of this files or to load nothing.

loadpatterns (patterns file) Loads the patterns file. Used by luababel.def.
loadexceptions (exceptions file) Loads the exceptions file. Used by
luababel.def.

\BabelContentsFiles

New 3.9a This macro contains a list of "toc" types which require a command to switch the language. Its default value is toc,lof,lot, but you may redefine it with \renewcommand (it's up to you to make sure no toc type is duplicated).

1.9 Hyphenation tools

\babelhyphen \babelhyphen

```
* {\langle type \rangle }
* {\langle text \rangle }
```

New 3.9a It is customary to classify hyphens in two types: (1) explicit or hard hyphens, which in T_EX are entered as -, and (2) optional or soft hyphens, which are entered as \-. Strictly, a soft hyphen is not a hyphen, but just a breaking oportunity or, in T_EX terms, a "discretionary"; a hard hyphen is a hyphen with a breaking oportunity after it. A further type is a non-breaking hyphen, a hyphen without a breaking oportunity.

In T_EX, - and \- forbid further breaking oportunities in the word. This is the desired behaviour very often, but not always, and therefore many languages provide shorthands for these cases. Unfortunately, this has not been done consistently: for example, in Dutch, Portugese, Catalan or Danish, "- is a hard hyphen, while in German, Spanish, Norwegian, Slovak or Russian, it is a soft hyphen. Furthermore, some of them even redefine \-, so that you cannot insert a soft hyphen without breaking oportunities in the rest of the word. Therefore, some macros are provide with a set of basic "hyphens" which can be used by themselves, to define a user shorthand, or even in language files.

- \babelhyphen{soft} and \babelhyphen{hard} are self explanatory.
- \babelhyphen{repeat} inserts a hard hyphen which is repeated at the beginning of the next line, as done in languages like Polish, Portugese and Spanish.
- \babelhyphen{nobreak} inserts a hard hyphen without a break after it (even if a space follows).
- \babelhyphen{empty} inserts a break oportunity without a hyphen at all.
- \babelhyphen{\langle text\rangle} is a hard "hyphen" using \langle text\rangle instead. A typical case is \babelhyphen{\langle}.

With all of them hyphenation in the rest of the word is enabled. If you don't want enabling it, there is a starred counterpart: $\begin{tabular}{l} \begin{tabular}{l} \begin{tabular}{$

\babelhyphenation

 $[\langle language \rangle, \langle language \rangle, ...] \{\langle exceptions \rangle\}$

New 3.9a Sets hyphenation exceptions for the languages given or, without the optional argument, for *all* languages (eg, proper nouns or common loan words, and of course monolingual documents). Language exceptions take precedence over global ones.

It can be used only in the preamble, and exceptions are set when the language is first selected, thus taking into account changes of \c done in \e tras $\langle lang \rangle$ as well as the language specific encoding (not set in the preamble by default). Multiple \b abelhyphenation's are allowed. For example:

```
\babelhyphenation{Wal-hal-la Dar-bhan-ga}
```

Listed words are saved expanded and therefore it relies on the LICR. Of course, it also works without the LICR if the input and the font encodings are the same, like in Unicode based engines.

\babelpatterns

 $[\langle language \rangle, \langle language \rangle, ...] \{\langle patterns \rangle\}$

New 3.9m In luatex only, 15 adds or replaces patterns for the languages given or, without the optional argument, for all languages. If a pattern for a certain combination already exists, it gets replaced by the new one.

It can be used only in the preamble, and patterns are added when the language is first selected, thus taking into account changes of \codes 's done in $\ensuremath{\codes}$'s well as the language specific encoding (not set in the preamble by default). Multiple $\ensuremath{\codes}$ babelpatterns's are allowed.

Listed patterns are saved expanded and therefore it relies on the LICR. Of course, it also works without the LICR if the input and the font encodings are the same, like in Unicode based engines.

1.10 Language attributes

\languageattribute

This is a user-level command, to be used in the preamble of a document (after \usepackage[...]{babel}), that declares which attributes are to be used for a given language. It takes two arguments: the first is the name of the language; the second, a (list of) attribute(s) to be used. Attributes must be set in the preamble and only once – they cannot be turned on and off. The command checks whether the language is known in this document and whether the attribute(s) are known for this language.

Very often, using a modifier in a package option is better.

Several language definition files use their own methods to set options. For example, frenchb uses \frenchbsetup, magyar (1.5) uses \magyarOptions; modifiers provided by spanish have no attribute counterparts. Macros settting options are also used (eg, \ProsodicMarksOn in latin).

1.11 Languages supported by babel

In the following table most of the languages supported by babel are listed, together with the names of the options which you can load babel with for each language. Note this list is open and the current options may be different.

Afrikaans afrikaans

¹⁵With luatex exceptions and patterns can be modified almost freely. However, this is very likely a task for a separate package and babel only provides the most basic tools.

Bahasa bahasa, indonesian, indon, bahasai, bahasam, malay, melayu

Basque basque Breton breton

Bulgarian bulgarian

Catalan catalan

Croatian croatian

Czech czech

Danish danish

Dutch dutch

English english, USenglish, american, UKenglish, british, canadian, australian, newzealand

Esperanto esperanto

Estonian estonian

Finnish finnish

French french, français, canadien, acadian

Galician galician

German austrian, german, germanb, ngerman, naustrian

Greek greek, polutonikogreek

Hebrew hebrew
Icelandic icelandic
Interlingua interlingua
Irish Gaelic irish

Italian italian
Latin latin

Lower Sorbian lowersorbian

North Sami samin

Norwegian norsk, nynorsk

Polish polish

Portuguese portuges, portuguese, brazilian, brazil

Romanian romanian

Russian russian

Scottish Gaelic scottish

Spanish spanish **Slovakian** slovak **Slovenian** slovene

Swedish swedish

Serbian serbian

Turkish turkish

Ukrainian ukrainian

Upper Sorbian uppersorbian

Welsh welsh

There are more languages not listed above, including hindi, thai, thaicjk, latvian, turkmen, magyar, mongolian, romansh, lithuanian, spanglish, vietnamese, japanese, pinyin, arabic, farsi, ibygreek, bgreek, serbianc, frenchle, ethiop and friulan.

Most of them work out of the box, but some may require extra fonts, encoding files, a preprocessor or even a complete framework (like CJK). For example, if you have got the velthuis/devnag package, you can create a file with extension .dn:

\documentclass{article}

\usepackage[hindi]{babel}

\begin{document}

```
{\dn devaanaa.m priya.h}
\end{document}
```

Then you preprocess it with devnag $\langle file \rangle$, which creates $\langle file \rangle$.tex; you can then typeset the latter with IATEX.

1.12 Tips, workarounds, know issues and notes

- If you use the document class book and you use \ref inside the argument of \chapter (or just use \ref inside \MakeUppercase), IATEX will keep complaining about an undefined label. To prevent such problems, you could revert to using uppercase labels, you can use \lowercase{\ref{foo}} inside the argument of \chapter, or, if you will not use shorthands in labels, set the safe option to none or bib.
- Both Itxdoc and babel use \AtBeginDocument to change some catcodes, and babel reloads hhline to make sure: has the right one, so if you want to change the catcode of | it has to be done using the same method at the proper place, with

```
\AtBeginDocument{\DeleteShortVerb{\|}}
```

before loading babel. This way, when the document begins the sequence is (1) make | active (ltxdoc); (2) make it unactive (your settings); (3) make babel shorthands active (babel); (4) reload hhline (babel, now with the correct catcodes for | and :).

 Documents with several input encodings are not frequent, but sometimes are useful. You can set different encodings for different languages as the following example shows:

```
\addto\extrasfrench{\inputencoding{latin1}}
\addto\extrasrussian{\inputencoding{koi8-r}}
```

(A recent version of inputenc is required.)

- For the hyphenation to work correctly, lccodes cannot change, because T_EX only takes into account the values when the paragraph is hyphenated, i.e., when it has been finished. Fo, if you write a chunk of French text with foreinglanguage, the apostrophes might not be taken into account. This is a limitation of T_EX , not of babel. Alternatively, you may use \useshorthands to activate and \defineshorthand, or redefine \textquoteright (the latter is called by the non-ASCII right quote).
- \bibitem is out of sync with \selectlanguage in the .aux file. The reason is \bibitem uses \immediate (and others, in fact), while \selectlanguage doesn't. There is no known workaround.
- Babel does not take into account \normalsfcodes and (non-)French spacing is not always properly (un)set by languages. However, problems are unlikely to happen and therefore this part remains untouched in version 3.9 (but it is in the 'to do' list).

¹⁶This explains why LATEX assumes the lowercase mapping of T1 and does not provide a tool for multiple mappings. Unfortunately, \savinghyphcodes is not a solution either, because locodes for hyphenation are frozen in the format and cannot be changed.

- Using a character mathematically active (ie, with math code "8000) as a shorthand can make T_EX enter in an infinite loop in some rare cases. (Another issue in the 'to do' list, although there is a partial solution.)
- Plain luatex does not load patterns on the fly. Since this format is not based on babel but on etex.src further investigation is required. This is another task in the 'to do' list.

The following packages can be useful, too (the list is still far from complete):

csquotes Logical markup for quotes.

iflang Tests correctly the current language.

hyphsubst Selects a different set of patterns for a language.

translator An open platform for packages that need to be localized.

siunitx Typesetting of numbers and physical quantities.

bibliatex Programmable bibliographies and citations.

bicaption Bilingual captions.

babelbib Multilingual bibliographies.

microtype Adjusts the typesetting according to some languages (kerning and spacing). Ligatures can be disabled.

substitutefont Combines fonts in several encodings.

mkpattern Generates hyphenation patterns.

1.13 Future work

Useful additions would be, for example, time, currency, addresses and personal names. 17 . But that is the easy part, because they don't require modifying the \LaTeX internals.

More interesting are differences in the sentence structure or related to it. For example, in Basque the number precedes the name (including chapters), in Hungarian "from (1)" is "(1)-ből", but "from (3)" is "(3)-ból", in Spanish an item labelled "3.°" may be referred to as either "ítem 3.°" or "3.er ítem", and so on. Even more interesting is right-to-left, vertical and bidi typesetting. Babel provided a basic support for bidi text as part of the style for Hebrew, but it is somewhat unsatisfactory and internally replaces some hardwired commands by other hardwired commands (generic changes would be much better).

Handling of "Unicode" fonts is also problematic. There is fontspec, but special macros are required (not only the NFSS ones) and it doesn't provide "orthogonal axis" for features, including those related to the language (mainly language and script). A couple of tentative macros, which solve the two main cases, are provided by babel ($\geq 3.9g$) with a partial solution (only xetex and luatex, for obvious reasons), but use them at your own risk, as they might be removed in the future. For this very reason, they are described here:

- \babelFSstore{ $\langle babel$ -language \rangle } sets the current three basic families (rm, sf, tt) as the default for the language given. In most cases, this macro will be enough.
- \babelFSdefault{ $\langle babel$ -language} \rangle }{ $\langle fontspec\text{-}features \rangle$ } patches \fontspec so that the given features are always passed as the optional argument or added to it (not an ideal solution). Use it only if you select some fonts in the document with \fontspec.

¹⁷See for example POSIX, ISO 14652 and the Unicode Common Locale Data Repository (CLDR).

So, for example:

```
\setmainfont[Language=Turkish]{Minion Pro}
\setsansfont[Language=Turkish]{Myriad Pro}
\babelFSstore{turkish}
\setmainfont{Minion Pro}
\setsansfont{Myriad Pro}
\babelFSfeatures{turkish}{Language=Turkish}
```

Note you can set any feature required for the language – not only Language, but also Script or a local . fea. This makes those macros a bit more verbose, but also more powerful.

2 Preloading languages with language.dat

 T_EX and most engines based on it (pdf T_EX , xetex, ϵ - T_EX , the main exception being luatex) require hyphenation patterns to be loaded when a format is created (eg, Latex, Xelatex, pdflatex), babel provides a tool which has become standard in many distributions and based on a "configuration file" named language.dat. The exact way this file is used depends on the distribution, so please, read the documentation for the latter (note also some distributions generate the file with some tool).

In that file the person who maintains a T_EX environment has to record for which languages he has hyphenation patterns and in which files these are stored 18 . When hyphenation exceptions are stored in a separate file this can be indicated by naming that file after the file with the hyphenation patterns.

The file can contain empty lines and comments, as well as lines which start with an equals (=) sign. Such a line will instruct LATEX that the hyphenation patterns just processed have to be known under an alternative name. Here is an example:

```
% File : language.dat
% Purpose : tell iniTeX what files with patterns to load.
english english.hyphenations
=british

dutch hyphen.dutch exceptions.dutch % Nederlands
german hyphen.ger
```

You may also set the font encoding the patterns are intended for by following the language name by a colon and the encoding code. ¹⁹ For example:

```
german:T1 hyphenT1.ger
german hyphen.ger
```

With the previous settings, if the enconding when the language is selected is T1 then the patterns in hyphenT1.ger are used, but otherwise use those in hyphen.ger (note the encoding could be set in \extras $\langle lang \rangle$).

A typical error when using babel is the following:

```
No hyphenation patterns were preloaded for the language '<lang>' into the format.
Please, configure your TeX system to add them and rebuild the format. Now I will use the patterns
```

¹⁸This is because different operating systems sometimes use *very* different file-naming conventions.

 $^{^{19}}$ This in not a new feature, but in former versions it didn't work correctly.

It simply means you must reconfigure language.dat, either by hand or with the tools provided by your distribution.

3 The interface between the core of babel and the language definition files

The language definition files (ldf) must conform to a number of conventions, because these files have to fill in the gaps left by the common code in babel.def, i.e., the definitions of the macros that produce texts. Also the language-switching possibility which has been built into the babel system has its implications. The following assumptions are made:

- Some of the language-specific definitions might be used by plain TEX users, so the files have to be coded so that they can be read by both LATEX and plain TEX. The current format can be checked by looking at the value of the macro \fmtname.
- The common part of the babel system redefines a number of macros and environments (defined previously in the document style) to put in the names of macros that replace the previously hard-wired texts. These macros have to be defined in the language definition files.
- The language definition files must define five macros, used to activate and deactivate the language-specific definitions. These macros are $\\langle lang \rangle$ hyphenmins, $\c lang \rangle$, $\c lang \rangle$, $\c lang \rangle$, $\c lang \rangle$ and $\c lang \rangle$ (the last two may be left empty); where $\c lang \rangle$ is either the name of the language definition file or the name of the LATEX option that is to be used. These macros and their functions are discussed below. You must define all or none for a language (or a dialect); defining, say, $\c lang \rangle$ but not $\c lang \rangle$ does not raise an error but can lead to unexpected results.
- When a language definition file is loaded, it can define \l@⟨lang⟩ to be a
 dialect of \language0 when \l@⟨lang⟩ is undefined.
- Language names must be all lowercase. If an unknow language is selected, babel will attempt setting it after lowercasing its name.
- The semantics of modifiers is not defined (on purpose). In most cases, they
 will just be simple separated options (eg., spanish), but a language might
 require, say, a set of options organized as a tree with suboptions (in such a
 case, the recommended separator is /).

Some recommendations:

• The preferred shorthand is ", which is not used in LATEX (quotes are entered as '' and ''). Other good choices are characters which are not used in a certain context (eg, = in an ancient language). Note however =, <, >, : and the like can be dangerous, because they may be used as part of the syntax of some elements (numeric expressions, key/value pairs, etc.).

- Captions should not contain shorthands or encoding dependent commands (the latter is not always possible, but should be clearly documented). They should be defined using the LICR. You may also use the new tools for encoded strings, described below.
- Avoid adding things to \noextras\(lang\) except for umlauthigh and friends, \bbl@deactivate, \bbl@(non) frenchspacing, and language specific macros. Use always, if possible, \bbl@save and \bbl@savevariable (except if you still want to have access to the previous value). Do not reset a macro or a setting to a hardcoded value. Never. Instead save its value in \extras\(lang\).
- Do not switch scripts. If you want to make sure a set of glyphs is used, switch either the font encoding (low level) or the language (high level, which in turn may switch the font encoding). Usage of things like \latintext is deprecated.²⁰

There are no special requirements for documenting your language files. Now they are not included in the base babel manual, so provide a standalone document suited for your needs (and the corresponding PDF, if you like), as well as other files you think can be useful (eg, samples, readme).

3.1 Basic macros

In the core of the babel system, several macros are defined for use in language definition files. Their purpose is to make a new language known. The first two are related to hyphenation patterns.

\addlanguage

The macro \addlanguage is a non-outer version of the macro \newlanguage, defined in plain.tex version 3.x. For older versions of plain.tex and lplain.tex a substitute definition is used. Here "language" is used in the T_EX sense of set of hyphenation patterns.

\adddialect

The macro \adddialect can be used when two languages can (or must) use the same hyphenation patterns. This can also be useful for languages for which no patterns are preloaded in the format. In such cases the default behaviour of the babel system is to define this language as a 'dialect' of the language for which the patterns were loaded as \language0. Here "language" is used in the T_EX sense of set of hyphenation patterns.

\<lang>hyphenmins

The macro $\langle lang \rangle$ hyphenmins is used to store the values of the $\label{lefthyphenmin}$ and $\label{lefthyphenmin}$. Redefine this macro to set your own values, with two numbers corresponding to these two parameters. For example:

\renewcommand\spanishhyphenmins{34}

(Assigning \lefthyphenmin and \righthyphenmin directly in \extras<lang> has no effect.)

\providehyphenmins

The macro \providehyphenmins should be used in the language definition files to set $\ensuremath{\mbox{lefthyphenmin}}$ and \providehyphenmin . This macro will check whether these parameters were provided by the hyphenation file before it takes any action. If these values have been already set, this command is ignored (currenty, default pattern files do not set them).

\captions \(lang \)

The macro \colong defines the macros that hold the texts to replace the original hard-wired texts.

extstyle ext

The macro $\langle lang \rangle$ defines $\langle today$.

\extras \(lang \)

The macro $\langle extras \langle lang \rangle$ contains all the extra definitions needed for a specific

 $^{^{\}rm 20} But$ not removed, for backward compatibility.

language. This macro, like the following, is a hook – you can add things to it, but it must not be used directly.

\noextras(lang)

Because we want to let the user switch between languages, but we do not know what state T_EX might be in after the execution of $\langle \text{extras} \langle \text{lang} \rangle$, a macro that brings T_EX into a predefined state is needed. It will be no surprise that the name of this macro is $\langle \text{lang} \rangle$.

\bbl@declare@ttribute

This is a command to be used in the language definition files for declaring a language attribute. It takes three arguments: the name of the language, the attribute to be defined, and the code to be executed when the attribute is to be used.

\main@language

To postpone the activation of the definitions needed for a language until the beginning of a document, all language definition files should use \main@language instead of \selectlanguage. This will just store the name of the language, and the proper language will be activated at the start of the document.

\ProvidesLanguage

The macro \ProvidesLanguage should be used to identify the language definition files. Its syntax is similar to the syntax of the LATEX command \ProvidesPackage . The macro \LdfInit performs a couple of standard checks that must be made at

\LdfInit

the beginning of a language definition file, such as checking the category code of the @-sign, preventing the .ldf file from being processed twice, etc.

\ldf@quit

The macro \ldf@quit does work needed if a .ldf file was processed earlier. This includes resetting the category code of the @-sign, preparing the language to be activated at \begin{document} time, and ending the input stream.

\ldf@finish

The macro \ldf@finish does work needed at the end of each .ldf file. This includes resetting the category code of the @-sign, loading a local configuration file, and preparing the language to be activated at \begin{document} time.

\loadlocalcfg

After processing a language definition file, LATEX can be instructed to load a local configuration file. This file can, for instance, be used to add strings to \captions $\langle lang \rangle$ to support local document classes. The user will be informed that this configuration file has been loaded. This macro is called by \ldf@finish.

\substitutefontfamily

(Deprecated.) This command takes three arguments, a font encoding and two font family names. It creates a font description file for the first font in the given encoding. This .fd file will instruct LATEX to use a font from the second family when a font from the first family in the given encoding seems to be needed.

3.2 Skeleton

Here is the basic structure of an ldf file, with a language, a dialect and an attribute. Strings are best defined using the method explained in in sec. ?? (babel 3.9 and later).

```
\ProvidesLanguage{<language>}
    [0000/00/00 v0.0 <Language> support from the babel system]
\LdfInit{<language>}{captions<language>}
\ifx\undefined\l@<language>
\@nopatterns{<Language>}
\adddialect\l@<language>0
\fi
\adddialect\l@<dialect>\l@<language>
\bbl@declare@ttribute{<language>}{<attrib>}{%
\expandafter\addto\expandafter\extras<language>
```

```
\expandafter{\extras<attrib><language>}%
 \let\captions<language>\captions<attrib><language>}
\providehyphenmins{<language>}{\tw@\thr@@}
\StartBabelCommands*{<language>}{captions}
\SetString\chaptername{<chapter name>}
\StartBabelCommands*{<language>}{date}
\SetString\monthiname{<name of first month>}
% More strings
\StartBabelCommands*{<dialect>}{captions}
\SetString\chaptername{<chapter name>}
% More strings
\StartBabelCommands*{<dialect>}{date}
\SetString\monthiname{<name of first month>}
% More strings
\EndBabelCommands
\addto\extras<language>{}
\addto\noextras<language>{}
\let\extras<dialect>\extras<language>
\let\noextras<dialect>\noextras<language>
\ldf@finish{<language>}
```

3.3 Support for active characters

In quite a number of language definition files, active characters are introduced. To facilitate this, some support macros are provided.

\initiate@active@char

The internal macro \inf active@char is used in language definition files to instruct LAT_EX to give a character the category code 'active'. When a character has been made active it will remain that way until the end of the document. Its definition may vary.

\bbl@activate
\bbl@deactivate

The command \bbl@activate is used to change the way an active character expands. \bbl@activate 'switches on' the active behaviour of the character. \bbl@deactivate lets the active character expand to its former (mostly) non-active self.

\declare@shorthand

The macro \declare@shorthand is used to define the various shorthands. It takes three arguments: the name for the collection of shorthands this definition belongs to; the character (sequence) that makes up the shorthand, i.e. ~ or "a; and the code to be executed when the shorthand is encountered. (It does *not* raise an error if the shorthand character has not been "initiated".)

\bbl@add@special \bbl@remove@special

The T_EX book states: "Plain T_EX includes a macro called \dospecials that is essentially a set macro, representing the set of all characters that have a special category code." [?, p. 380] It is used to set text 'verbatim'. To make this work if more characters get a special category code, you have to add this character to the macro \dospecial. \LaTeX adds another macro called \@sanitize representing the same character set, but without the curly braces. The macros

\bbl@add@special $\langle char \rangle$ and \bbl@remove@special $\langle char \rangle$ add and remove the character $\langle char \rangle$ to these two sets.

3.4 Support for saving macro definitions

Language definition files may want to redefine macros that already exist. Therefore a mechanism for saving (and restoring) the original definition of those macros is provided. We provide two macros for this²¹.

\babel@save

To save the current meaning of any control sequence, the macro \babel@save is provided. It takes one argument, $\langle csname \rangle$, the control sequence for which the meaning has to be saved.

\babel@savevariable

A second macro is provided to save the current value of a variable. In this context, anything that is allowed after the \t the primitive is considered to be a variable. The macro takes one argument, the $\langle variable \rangle$.

The effect of the preceding macros is to append a piece of code to the current definition of \originalTeX. When \originalTeX is expanded, this code restores the previous definition of the control sequence or the previous value of the variable.

3.5 Support for extending macros

\addto

The macro \addto{ $\langle control\ sequence \rangle$ }{ $\langle T_EX\ code \rangle$ } can be used to extend the definition of a macro. The macro need not be defined (ie, it can be undefined or \relax). This macro can, for instance, be used in adding instructions to a macro like \extrasenglish.

Be careful when using this macro, because depending on the case the assignment could be either global (usually) or local (sometimes). That does not seem very consistent, but this behaviour is preserved for backward compatibility. If you are using etoolbox, by Philipp Lehman, consider using the tools provided by this package instead of \addto.

3.6 Macros common to a number of languages

\bbl@allowhyphens

In several languages compound words are used. This means that when $T_E X$ has to hyphenate such a compound word, it only does so at the '-' that is used in such words. To allow hyphenation in the rest of such a compound word, the macro \bbl@allowhyphens can be used.

\allowhyphens

Same as \bbl@allowhyphens, but does nothing if the encoding is T1. It is intended mainly for characters provided as real glyphs by this encoding but constructed with \accent in OT1.

Note the previous command (\bbl@allowhyphens) has different applications (hyphens and discretionaries) than this one (composite chars). Note also prior to version 3.7, \allowhyphens had the behaviour of \bbl@allowhyphens.

\set@low@box

For some languages, quotes need to be lowered to the baseline. For this purpose the macro $\set@low@box$ is available. It takes one argument and puts that argument in an $\box0$ for further processing.

\save@sf@q

Sometimes it is necessary to preserve the \spacefactor. For this purpose the macro \save@sf@q is available. It takes one argument, saves the current spacefactor, executes the argument, and restores the spacefactor.

²¹This mechanism was introduced by Bernd Raichle.

\bbl@frenchspacing \bbl@nonfrenchspacing

The commands \bbl@frenchspacing and \bbl@nonfrenchspacing can be used to properly switch French spacing on and off.

3.7 Encoding-dependent strings

New 3.9a Babel 3.9 provides a way of defining strings in several encodings, intended mainly for luatex and xetex. This is the only new feature requiring changes in language files if you want to make use of it.

Furthermore, it must be activated explicitly, with the package option strings. If there is no strings, these blocks are ignored, except \SetCases (and except if forced as described below). In other words, the old way of defining/switching strings still works and it's used by default.

It consist is a series of blocks started with \StartBabelCommands. The last block is closed with \EndBabelCommands. Each block is a single group (ie, local declarations apply until the next \StartBabelCommands or \EndBabelCommands). An ldf may contain several series of this kind.

Thanks to this new feature, string values and string language switching are not mixed any more. No need of \addto. If the language is french, just redefine \frenchchaptername.

\StartBabelCommands

 ${\langle language-list \rangle} {\langle category \rangle} [\langle selector \rangle]$

The $\langle language-list \rangle$ specifies which languages the block is intended for. A block is taken into account only if the $\backslash CurrentOption$ is listed here. Alternatively, you can define $\backslash BabelLanguages$ to a comma-separated list of languages to be defined (if undefined, $\backslash StartBabelCommands$ sets it to $\backslash CurrentOption$). You may write $\backslash CurrentOption$ as the language, but this is discouraged – a explicit name (or names) is much better and clearer.

A "selector" is a name to be used as value in package option strings, optionally followed by extra info about the encodings to be used. The name unicode must be used for xetex and luatex (the key strings has also other two special values: generic and encoded).

If a string is set several times (because several blocks are read), the first one take precedence (ie, it works much like \providecommand).

Encoding info is charset= followed by a charset, which if given sets how the strings should be traslated to the internal representation used by the engine, typically utf8, which is the only value supported currently (default is no traslations). Note charset is applied by luatex and xetex when reading the file, not when the macro or string is used in the document.

A list of font encodings which the strings are expected to work with can be given after fontenc= (separated with spaces, if two or more) – recommended, but not mandatory, although blocks without this key are not taken into account if you have requested strings=encoded.

Blocks without a selector are read always if the key strings has been used. They provide fallback values, and therefore must be the last blocks; they should be provided always if possible and all strings should be defined somehow inside it; they can be the only blocks (mainly LGC scripts using the LICR). Blocks without a selector can be activated explicitly with strings=generic (no block is taken into account except those). With strings=encoded, strings in those blocks are set as default (internally, ?). With strings=encoded strings are protected, but they are correctly expanded in \MakeUppercase and the like. If there is no key strings, string definitions are ignored, but \SetCases are still honoured (in a encoded way).

The $\langle category \rangle$ is either captions, date or extras. You must stick to these three categories, even if no error is raised when using other name.²² It may be empty, too, but in such a case using \SetString is an error (but not \SetCase).

```
\StartBabelCommands{language}{captions}
  [unicode, fontenc=EU1 EU2, charset=utf8]
\SetString{\chaptername}{utf8-string}

\StartBabelCommands{language}{captions}
\SetString{\chaptername}{ascii-maybe-LICR-string}

\EndBabelCommands
```

A real example is:

```
\StartBabelCommands{austrian}{date}
  [unicode, fontenc=EU1 EU2, charset=utf8]
 \SetString\monthiname{Jänner}
\StartBabelCommands{german,austrian}{date}
  [unicode, fontenc=EU1 EU2, charset=utf8]
 \SetString\monthiiiname{März}
\StartBabelCommands{austrian}{date}
 \SetString\monthiname{J\"{a}nner}
\StartBabelCommands{german}{date}
 \SetString\monthiname{Januar}
\StartBabelCommands{german,austrian}{date}
  \SetString\monthiiname{Februar}
 \SetString\monthiiiname{M\"{a}rz}
 \SetString\monthivname{April}
 \SetString\monthvname{Mai}
 \SetString\monthviname{Juni}
  \SetString\monthviiname{Juli}
  \SetString\monthviiiname{August}
 \SetString\monthixname{September}
 \SetString\monthxname{0ktober}
 \SetString\monthxiname{November}
  \SetString\monthxiiname{Dezenber}
 \SetString\today{\number\day.~%
    \csname month\romannumeral\month name\endcsname\space
    \number\year}
\StartBabelCommands{german,austrian}{captions}
  \SetString\prefacename{Vorwort}
  [etc.]
\EndBabelCommands
```

When used in ldf files, previous values of $\langle category \rangle \langle language \rangle$ are overriden, which means the old way to define strings still works and used by default (to be precise, is first set to undefined and then strings are added). However, when used in the preamble or in a package, new settings are added to the previous ones, if the language exists (in the babel sense, ie, if $\langle language \rangle$ exists).

²²In future releases further categories may be added.

\StartBabelCommands

```
*\{\langle language-list \rangle\}\{\langle category \rangle\}[\langle selector \rangle]
```

The starred version just forces strings to take a value - if not set as package option, then the default for the engine is used. This is not done by default to prevent backward incompatibilities, but if you are creating a new language this version is better. It's up to the maintainers of the current languages to decide if using it is appropriate.²³

\EndBabelCommands

Marks the end of the series of blocks.

\AfterBabelCommands

```
\{\langle code \rangle\}
```

The code is delayed and executed at the global scope just after \EndBabelCommands.

\SetString

```
\{\langle macro-name \rangle\}\{\langle string \rangle\}
```

Adds (*macro-name*) to the current category, and defines globally $\langle lang\text{-}macro\text{-}name \rangle$ to $\langle code \rangle$ (after applying the transformation corresponding to the current charset or defined with the hook stringprocess).

Use this command to define strings, without including any "logic" if possible, which should be a separated macro. See the example above for the date.

\SetStringLoop

```
\{\langle macro-name \rangle\}\{\langle string-list \rangle\}
```

A convenient way to define several ordered names at once. For example, to define \abmoniname, \abmoniiname, etc. (and similarly with abday):

```
\SetStringLoop{abmon#1name}{en,fb,mr,ab,my,jn,jl,ag,sp,oc,nv,dc}
\SetStringLoop{abday#1name}{lu,ma,mi,ju,vi,sa,do}
```

#1 is replaced by the roman numeral.

```
\SetCase [\langle map-list \rangle] \{\langle toupper-code \rangle\} \{\langle tolower-code \rangle\}
```

Sets globally code to be executed at \MakeUppercase and \MakeLowercase. The code would be typically things like \let\BB\bb and \uccode or \lccode (although for the reasons explained above, changes in lc/uc codes may not work). A (map-list) is a series of macros using the internal format of \@uclclist (eg, \bb\BB\cc\CC). The mandatory arguments take precedence over the optional one. This command, unlike \SetString, is executed always (even without strings), and it is intented for minor readjustments only.

For example, as T1 is the default case mapping in LATEX, we could set for Turkish:

```
\StartBabelCommands{turkish}{}[otlenc, fontenc=OT1]
\SetCase
  {\uccode"10='I\relax}
  {\lccode'I="10\relax}
\StartBabelCommands{turkish}{}[unicode, fontenc=EU1 EU2, charset=utf8]
  {\uccode'i='İ\relax
   \uccode'1='I\relax}
  {\lccode'İ='i\relax
  \lccode'I='1\relax}
```

 $^{^{23}}$ This replaces in 3.9g a short-lived \UseStrings which has been removed because it did not work.

```
\StartBabelCommands{turkish}{}
\SetCase
    {\uccode'i="9D\relax
     \uccode"19='I\relax}
    {\lccode"9D='i\relax
     \lccode'I="19\relax}
\EndBabelCommands
```

(Note the mapping for **OT1** is not complete.)

\SetHyphenMap

 $\{\langle to\text{-}lower\text{-}macros \rangle\}$

New 3.9g Case mapping serves in T_EX for two unrelated purposes: case transforms (upper/lower) and hyphenation. \SetCase handles the former, while hyphenation is handled by \SetHyphenMap and controlled with the package option hyphenmap. So, even if internally they are based on the same T_EX primitive (\lccode), babel sets them separately.

There are three helper macros to be used inside \SetHyphenMap:

- \BabelLower{\langle uccode \rangle} \{\langle lccode \rangle}\} is similar to \lccode but it's ignored if the char has been set and saves the original lccode to restore it when switching the language (except with hyphenmap=first).
- \BabelLowerMM{ $\langle uccode-from \rangle$ }{ $\langle uccode-to \rangle$ }{ $\langle step \rangle$ }{ $\langle lccode-from \rangle$ } loops though the given uppercase codes, using the step, and assigns them the lccode, which is also increased (MM stands for many-to-many).
- \BabelLowerMO{ $\langle uccode-from \rangle$ }{ $\langle uccode-to \rangle$ }{ $\langle step \rangle$ }{ $\langle lccode \rangle$ } loops though the given uppercase codes, using the step, and assigns them the lccode, which is fixed (MO stands for many-to-one).

An example is (which is redundant, because these assignments are done by both luatex and xetex):

```
\label{lowerMM} $$ \SetHyphenMap{BabelLowerMM{"100}{"11F}{2}{"101}} $$
```

This macro is not intended to fix wrong mappings done by Unicode (which are the default in both xetex and luatex) – if an assignment is wrong, fix it directly.

4 Compatibility and changes

4.1 Compatibility with german.sty

The file german.sty has been one of the sources of inspiration for the babel system. Because of this I wanted to include german.sty in the babel system. To be able to do that I had to allow for one incompatibility: in the definition of the macro \selectlanguage in german.sty the argument is used as the $\langle number \rangle$ for an \ifcase. So in this case a call to \selectlanguage might look like \selectlanguage{\quad qerman}.

In the definition of the macro \selectlanguage in babel.def the argument is used as a part of other macronames, so a call to \selectlanguage now looks like \selectlanguage{german}. Notice the absence of the escape character. As of version 3.1a of babel both syntaxes are allowed.

All other features of the original german.sty have been copied into a new file, called germanb. sty^{24} .

Although the babel system was developed to be used with \LaTeX X, some of the features implemented in the language definition files might be needed by plain \Tau X users. Care has been taken that all files in the system can be processed by plain \Tau X.

4.2 Compatibility with ngerman.sty

When used with the options ngerman or naustrian, babel will provide all features of the package ngerman. There is however one exception: The commands for special hyphenation of double consonants ("ff etc.) and ck ("ck), which are no longer required with the new German orthography, are undefined. With the ngerman package, however, these commands will generate appropriate warning messages only.

4.3 Compatibility with the french package

It has been reported to me that the package french by Bernard Gaulle (gaulle@idris.fr) works together with babel. On the other hand, it seems *not* to work well together with a lot of other packages. Therefore I have decided to no longer load french.ldf by default. Instead, when you want to use the package by Bernard Gaulle, you will have to request it specifically, by passing either frenchle or frenchpro as an option to babel.

4.4 Changes in babel version 3.9

Most of changes in version 3.9 are related to bugs, either to fix them (there were lots), or to provide some alternatives. Even new features like \babelhyphen are intended to solve a certain problem (in this case, the lacking of a uniform syntax and behaviour for shorthands across languages). These changes are described in this manual in the correspondin place.

4.5 Changes in babel version 3.7

In babel version 3.7 a number of bugs that were found in version 3.6 are fixed. Also a number of changes and additions have occurred:

- Shorthands are expandable again. The disadvantage is that one has to type
 '{}a when the acute accent is used as a shorthand character. The advantage
 is that a number of other problems (such as the breaking of ligatures, etc.)
 have vanished.
- Two new commands, \shorthandon and \shorthandoff have been introduced to enable to temporarily switch off one or more shorthands.
- Support for typesetting Greek has been enhanced. Code from the kdgreek package (suggested by the author) was added and \greeknumeral has been added.
- Support for typesetting Basque is now available thanks to Juan Aguirregabiria.

 $^{^{24}\}mbox{The}$ 'b' is added to the name to distinguish the file from Partls' file.

- Support for typesetting Serbian with Latin script is now available thanks to Dejan Muhamedagić and Jankovic Slobodan.
- Support for typesetting Hebrew (and potential support for typesetting other right-to-left written languages) is now available thanks to Rama Porrat and Boris Lavva.
- Support for typesetting Bulgarian is now available thanks to Georgi Boshnakov.
- Support for typesetting Latin is now available, thanks to Claudio Beccari and Krzysztof Konrad Żelechowski.
- Support for typesetting North Sami is now available, thanks to Regnor Jernsletten.
- The options canadian, canadien and acadien have been added for Canadian English and French use.
- A language attribute has been added to the \mark... commands in order to make sure that a Greek header line comes out right on the last page before a language switch.
- Hyphenation pattern files are now read inside a group; therefore any
 changes a pattern file needs to make to lowercase codes, uppercase codes,
 and category codes are kept local to that group. If they are needed for the
 language, these changes will need to be repeated and stored in \extras...
- The concept of language attributes is introduced. It is intended to give the user some control over the features a language-definition file provides. Its first use is for the Greek language, where the user can choose the $\pi o \lambda v \tau o \nu \kappa \delta$ ("Polutoniko" or multi-accented) Greek way of typesetting texts. These attributes will possibly find wider use in future releases.
- The environment hyphenrules is introduced.
- The syntax of the file language.dat has been extended to allow (optionally) specifying the font encoding to be used while processing the patterns file.
- The command \providehyphenmins should now be used in language definition files in order to be able to keep any settings provided by the pattern file.

4.6 Changes in babel version 3.6

In babel version 3.6 a number of bugs that were found in version 3.5 are fixed. Also a number of changes and additions have occurred:

- A new environment otherlanguage* is introduced. it only switches the 'specials', but leaves the 'captions' untouched.
- The shorthands are no longer fully expandable. Some problems could only be solved by peeking at the token following an active character. The advantage is that '{}a works as expected for languages that have the 'active.
- Support for typesetting french texts is much enhanced; the file francais.ldf is now replaced by frenchb.ldf which is maintained by Daniel Flipo.

- Support for typesetting the russian language is again available. The
 language definition file was originally developed by Olga Lapko from
 CyrTUG. The fonts needed to typeset the russian language are now part of
 the babel distribution. The support is not yet up to the level which is needed
 according to Olga, but this is a start.
- Support for typesetting greek texts is now also available. What is offered in this release is a first attempt; it will be enhanced later on by Yannis Haralambous.
- in babel 3.6j some hooks have been added for the development of support for Hebrew typesetting.
- Support for typesetting texts in Afrikaans (a variant of Dutch, spoken in South Africa) has been added to dutch.ldf.
- Support for typesetting Welsh texts is now available.
- A new command \aliasshorthand is introduced. It seems that in Poland various conventions are used to type the necessary Polish letters. It is now possible to use the character / as a shorthand character instead of the character ", by issuing the command \aliasshorthand{"}{/}.
- The shorthand mechanism now deals correctly with characters that are already active.
- Shorthand characters are made active at \begin{document}, not earlier. This
 is to prevent problems with other packages.
- A preambleonly command \substitutefontfamily has been added to create .fd files on the fly when the font families of the Latin text differ from the families used for the Cyrillic or Greek parts of the text.
- Three new commands \LdfInit, \ldf@quit and \ldf@finish are introduced that perform a number of standard tasks.
- In babel 3.6k the language Ukrainian has been added and the support for Russian typesetting has been adapted to the package 'cyrillic' to be released with the December 1998 release of LATEX 2_{E} .

4.7 Changes in babel version 3.5

In babel version 3.5 a lot of changes have been made when compared with the previous release. Here is a list of the most important ones:

- the selection of the language is delayed until \begin{document}, which
 means you must add appropriate \selectlanguage commands if you include
 \hyphenation lists in the preamble of your document.
- babel now has a language environment and a new command \foreignlanguage;
- the way active characters are dealt with is completely changed. They are
 called 'shorthands'; one can have three levels of shorthands: on the user
 level, the language level, and on 'system level'. A consequence of the new
 way of handling active characters is that they are now written to auxiliary
 files 'verbatim';

- A language change now also writes information in the .aux file, as the change might also affect typesetting the table of contents. The consequence is that an .aux file generated by a LATEXformat with babel preloaded gives errors when read with a LATEXformat without babel; but I think this probably doesn't occur;
- babel is now compatible with the inputenc and fontenc packages;
- the language definition files now have a new extension, ldf;
- the syntax of the file language.dat is extended to be compatible with the french package by Bernard Gaulle;
- each language definition file looks for a configuration file which has the same name, but the extension .cfg. It can contain any valid LATEX code.

Part II

The code

5 Identification and loading of required files

Code documentation is still under revision.

The babel package after unpacking it consists of the following files:

switch.def defines macros to set and switch languages.

babel.def defines the rest of macros. It has tow parts: a generic one and a second one only for LaTeX.

 $\label{eq:babel.sty} \textbf{babel.sty} \ \ \text{is the LAT}_{E\!X} \ package, \ which set options and load language styles. \\ \textbf{plain.def} \ \ defines \ some \ \ \text{LAT}_{E\!X} \ macros \ required \ by \ babel.def \ and \ provides \ a few$

hyphen.cfg is the file to be used when generating the formats to load hyphenation patterns. By default it also loads switch.def.

The babel installer extends docstrip with a few "pseudo-guards" to set "variables" used at installation time. They are used with <@name@> at the appropriated places in the source code and shown below with $\langle \langle name \rangle \rangle$. That brings a little bit of literate programming.

```
\begin{array}{l} 1 \left<\left< version = 3.9m \right>\right> \\ 2 \left<\left< date = 2016/01/05 \right>\right> \end{array}
```

tools for Plain.

We define some basic macros which just make the code cleaner. \bbl@add is now used internally instead of \addto because of the unpredictable behaviour of the latter. Used in babel.def and in babel.sty, which means in \LaTeX is executed twice, but we need them when defining options and babel.def cannot be load until options have been defined.

```
3 \(\langle\text{Basic macros}\rangle \equiv 
4 \def\bbl@add#1#2{\rangle\text{bble\text{string#1}\rangle\rangle}}
5 \@ifundefined{\expandafter\@gobble\string#1}\rangle\rangle}
6 \{\def\text{def#1{#2}}\rangle\rangle}
7 \{\expandafter\def\expandafter#1\expandafter{#1#2}}\rangle\rangle\rangle\text{bble\text{csname}}\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rangle\rang
```

```
10 \long\def\bbl@afterfi#1\fi{\fi#1}
11 \def\bbl@loop#1#2#3{\bbl@loop#1{#3}#2,\@nnil,}
12 \def\bbl@loopx#1#2{\expandafter\bbl@loop\expandafter#1\expandafter{#2}}
13 \def\bbl@@loop#1#2#3,{%
14 \ifx\@nnil#3\relax\else
15 \def#1{#3}#2\bbl@afterfi\bbl@@loop#1{#2}%
16 \fi}
17 \def\bbl@for#1#2#3{\bbl@loopx#1{#2}{\ifx#1\@empty\else#3\fi}}
18 \langle \langle Basic macros\rangle
\end{align*}
```

Some files identify themselves with a LATEX macro. The following code is placed before them to define (and then undefine) if not in LATEX.

```
19 ⟨⟨*Make sure ProvidesFile is defined⟩⟩ ≡
20 \ifx\ProvidesFile\@undefined
21 \def\ProvidesFile#1[#2 #3 #4]{%
22 \wlog{File: #1 #4 #3 <#2>}%
23 \let\ProvidesFile\@undefined}
24 \fi
25 ⟨⟨/Make sure ProvidesFile is defined⟩⟩
```

The following code is used in babel.sty and babel.def, and makes sure the current version of switch.ldf is used, if different from that in the format.

The following code is used in babel.def and switch.def.

```
32 ⟨⟨*Load macros for plain if not LaTeX⟩⟩ ≡
33 \ifx\AtBeginDocument\@undefined
34 \input plain.def\relax
35 \fi
36 ⟨⟨/Load macros for plain if not LaTeX⟩⟩
```

5.1 Multiple languages

\language

Plain T_EX version 3.0 provides the primitive \language that is used to store the current language. When used with a pre-3.0 version this function has to be implemented by allocating a counter. The following block is used in switch.def and hyphen.cfg; the latter may seem redundant, but remember babel doesn't requires loading switch.def in the format.

```
37 ⟨⟨*Define core switching macros⟩⟩ ≡
38 \ifx\language\@undefined
39 \csname newcount\endcsname\language
40 \fi
41 ⟨⟨/Define core switching macros⟩⟩
```

\last@language

Another counter is used to store the last language defined. For pre-3.0 formats an extra counter has to be allocated.

\addlanguage

To add languages to T_EX 's memory plain T_EX version 3.0 supplies \newlanguage, in a pre-3.0 environment a similar macro has to be provided. For both cases a new macro is defined here, because the original \newlanguage was defined to be \outer.

For a format based on plain version 2.x, the definition of \newlanguage can not be copied because \count 19 is used for other purposes in these formats. Therefore \addlanguage is defined using a definition based on the macros used to define \newlanguage in plain T_EX version 3.0.

For formats based on plain version 3.0 the definition of \newlanguage can be simply copied, removing \outer. Plain T_EX version 3.0 uses \count 19 for this purpose.

```
42 \langle * \text{Define core switching macros} \rangle \equiv
43 \ifx\newlanguage\@undefined
     \csname newcount\endcsname\last@language
     \def\addlanguage#1{%
45
        \global\advance\last@language\@ne
46
        \ifnum\last@language<\@cclvi
47
        \else
48
             \errmessage{No room for a new \string\language!}%
49
50
        \fi
        \global\chardef#1\last@language
51
        \wlog{\string#1 = \string\language\the\last@language}}
52
53 \else
     \countdef\last@language=19
     \def\addlanguage{\alloc@9\language\chardef\@cclvi}
56\fi
57 ((/Define core switching macros))
Identify each file that is produced from this source file.
58 (*driver&!user)
59 \ProvidesFile{babel.drv} [\langle\langle date\rangle\rangle\ \langle\langle version\rangle\rangle]
60 (/driver&!user)
61 (*driver & user)
62 \ProvidesFile{user.drv}[\langle \langle date \rangle \rangle \ \langle \langle version \rangle \rangle]
63 (/driver & user)
```

Now we make sure all required files are loaded. When the command \AtBeginDocument doesn't exist we assume that we are dealing with a plain-based format or LATEX2.09. In that case the file plain.def is needed (which also defines \AtBeginDocument, and therefore it is not loaded twice). We need the first part when the format is created, and \orig@dump is used as a flag. Otherwise, we need to use the second part, so \orig@dump is not defined (plain.def undefines it). Check if the current version of switch.def has been previously loaded (mainly, hyphen.cfg). If not, load it now. We cannot load babel.def here because we first need to declare and process the package options.

6 The Package File (LATEX)

In order to make use of the features of LATEX $2_{\mathcal{E}}$, the babel system contains a package file, babel.sty. This file is loaded by the \usepackage command and defines all the language options whose name is different from that of the .ldf file (like variant spellings). It also takes care of a number of compatibility issues with other packages an defines a few additional package options.

Apart from all the language options below we also have a few options that influence the behaviour of language definition files.

Many of the following options don't do anything themselves, they are just defined in order to make it possible for babel and language definition files to check if one of them was specified by the user.

6.1 base

The first option to be processed is base, which set the hyphenation patterns then resets ver@babel.sty so that $\text{LAT}_{E}X$ forgets about the first loading. After switch.def has been loaded (above) and AfterBabelLanguage defined, exits.

```
64 (*package)
65 \NeedsTeXFormat{LaTeX2e}[2005/12/01]
66 \ProvidesPackage{babel}[\langle\langle date\rangle\rangle \langle\langle version\rangle\rangle The Babel package]
67 \@ifpackagewith{babel}{debug}
68 {\input switch.def\relax}
69 \{\langle\langle Load\ switch\ if\ newer
angle\rangle\}
70 \langle \langle Basic\ macros \rangle \rangle
71 \def\AfterBabelLanguage#1{%
   \qlobal\expandafter\bbl@add\csname#1.ldf-h@@k\endcsname}%
73 \@ifpackagewith{babel}{base}{%
    \DeclareOption*{\bbl@patterns{\CurrentOption}}%
   \DeclareOption{base}{}%
    \ProcessOptions
    \qlobal\expandafter\let\csname opt@babel.sty\endcsname\relax
   \global\expandafter\let\csname ver@babel.sty\endcsname\relax
    \global\let\@ifl@ter@@\@ifl@ter
    \def\@ifl@ter#1#2#3#4#5{\global\let\@ifl@ter\@ifl@ter@@}%
    \endinput}{}%
```

6.2 key=value options and other general option

The following macros extract language modifiers, and only real package options are kept in the option list. Modifiers are saved and assigned to \BabelModifiers at \bbl@load@language; when no modifiers have been given, the former is \relax. How modifiers are handled are left to language styles; they can use \in@, loop them with \@for o load keyval).

```
82 \bbl@csarg\let{tempa\expandafter}\csname opt@babel.sty\endcsname
83 \def\bbl@tempb#1.#2{%
     #1\ifx\@empty#2\else,\bbl@afterfi\bbl@tempb#2\fi}%
85 \def\bbl@tempd#1.#2\@nnil{%
   \ifx\@empty#2%
      \edef\bbl@tempc{\ifx\bbl@tempc\@empty\else\bbl@tempc,\fi#1}%
87
88
   \else
      \left( \frac{1}{2} \right) 
89
        \edef\bbl@tempc{\ifx\bbl@tempc\@empty\else\bbl@tempc,\fi#1.#2}%
90
91
        \edef\bbl@tempc{\ifx\bbl@tempc\@empty\else\bbl@tempc,\fi#1}%
92
        \bbl@csarg\edef{mod@#1}{\bbl@tempb#2}%
93
      \fi
   \fi}
95
96 \let\bbl@tempc\@empty
97 \bbl@for\bbl@tempa\bbl@tempa{%
    \expandafter\bbl@tempd\bbl@tempa.\@empty\@nnil}
99 \expandafter\let\csname opt@babel.sty\endcsname\bbl@tempc
```

The next option tells babel to leave shorthand characters active at the end of processing the package. This is *not* the default as it can cause problems with other packages, but for those who want to use the shorthand characters in the preamble of their documents this can help.

```
100 \DeclareOption{KeepShorthandsActive}{}
```

```
101 \DeclareOption{activeacute}{}
102 \DeclareOption{activegrave}{}
103 \DeclareOption{debug}{}
104 \DeclareOption{noconfigs}{}
105 \DeclareOption{showlanguages}{}
106 \DeclareOption{silent}{}
107 \DeclareOption{shorthands=off}{\bbl@tempa shorthands=\bbl@tempa}
108 \(\lambda More package options \rangle \rangle
\]
```

Handling of package options is done in three passes. (I [JBL] am not very happy with the idea, anyway.) The first one processes options which has been declared above or follow the syntax <key>=<value>, the second one loads the requested languages, except the main one if set with the key main, and the third one loads the latter. First, we "flag" valid keys with a nil value.

```
109 \let\bbl@opt@shorthands\@nnil
110 \let\bbl@opt@config\@nnil
111 \let\bbl@opt@main\@nnil
112 \let\bbl@opt@headfoot\@nnil
```

The following tool is defined temporarily to store the values of options.

```
113 \def\bbl@tempa#1=#2\bbl@tempa{%
    \expandafter\ifx\csname bbl@opt@#1\endcsname\@nnil
115
       \expandafter\edef\csname bbl@opt@#1\endcsname{#2}%
    \else
116
      \bbl@error{%
117
         Bad option '#1=#2'. Either you have misspelled the\\%
118
         key or there is a previous setting of '#1'}{%
119
         Valid keys are 'shorthands', 'config', 'strings', 'main',\\%
120
121
         'headfoot', 'safe', 'math'}
122
    \fi}
```

Now the option list is processed, taking into account only currently declared options (including those declared with a =), and <key>=<value> options (the former take precedence). Unrecognized options are saved in \bbl@language@opts, because they are language options.

```
123 \let\bbl@language@opts\@empty
124 \DeclareOption*{%
125 \@expandtwoargs\in@{\string=}{\CurrentOption}%
126 \ifin@
127 \expandafter\bbl@tempa\CurrentOption\bbl@tempa
128 \else
129 \edef\bbl@language@opts{%
130 \ifx\bbl@language@opts\@empty\else\bbl@language@opts,\fi
131 \CurrentOption}%
132 \fi}
```

Now we finish the first pass (and start over).

133 \ProcessOptions*

6.3 Conditional loading of shorthands

If there is no shorthands=<chars>, the original babel macros are left untouched, but if there is, these macros are wrapped (in babel.def) to define only those given. A bit of optimization: if there is no shorthands=, then \bbl@ifshorthands is always true, and it is always false if shorthands is empty. Also, some code makes sense only with shorthands=....

```
134 \def\bbl@sh@string#1{%
    \ifx#1\@empty\else
       \ifx#1t\string~%
136
       \else\ifx#1c\string,%
137
       \else\string#1%
138
       \fi\fi
139
       \expandafter\bbl@sh@string
140
141
    \fi}
142 \ifx\bbl@opt@shorthands\@nnil
    \def\bbl@ifshorthand#1#2#3{#2}%
144 \else\ifx\bbl@opt@shorthands\@empty
    \def\bbl@ifshorthand#1#2#3{#3}%
146 \else
```

The following macro tests if a shortand is one of the allowed ones.

```
147 \def\bbl@ifshorthand#1{%
148 \@expandtwoargs\in@{\string#1}{\bbl@opt@shorthands}%
149 \ifin@
150 \expandafter\@firstoftwo
151 \else
152 \expandafter\@secondoftwo
153 \fi}
```

We make sure all chars in the string are 'other', with the help of an auxiliary macro defined above (which also zaps spaces).

```
154 \edef\bbl@opt@shorthands{%
155 \expandafter\bbl@sh@string\bbl@opt@shorthands\@empty}%
```

The following is ignored with shorthands=off, since it is intended to take some aditional actions for certain chars.

```
156 \bbl@ifshorthand{'}%
157 {\PassOptionsToPackage{activeacute}{babel}}{}
158 \bbl@ifshorthand{'}%
159 {\PassOptionsToPackage{activegrave}{babel}}{}
160 \fi\fi
```

With headfoot=lang we can set the language used in heads/foots. For example, in babel/3796 just adds headfoot=english. It misuses \@resetactivechars but seems to work.

```
161 \ifx\bbl@opt@headfoot\@nnil\else
162 \g@addto@macro\@resetactivechars{%
163 \set@typeset@protect
164 \expandafter\select@language@x\expandafter{\bbl@opt@headfoot}%
165 \let\protect\noexpand}
166 \fi
```

For the option safe we use a different approach – \bbl@opt@safe says which macros are redefined (B for bibs and R for refs). By default, both are set.

```
167 \@ifundefined{bbl@opt@safe}{\def\bbl@opt@safe{BR}}{}
168 \ifx\bbl@opt@main\@nnil\else
169 \edef\bbl@language@opts{%
170 \ifx\bbl@language@opts\@empty\else\bbl@language@opts,\fi
171 \bbl@opt@main}
172 \fi
```

If the format created a list of loaded languages (in \bbl@languages), get the name of the 0-th to show the actual language used.

```
173 \ifx\bbl@languages\@undefined\else
```

```
\begingroup
174
                                                              \catcode'\^^I=12
175
                                                              \@ifpackagewith{babel}{showlanguages}{%
176

185
                                                                                \gdef\bbl@nulllanguage{#1}%
186
187
                                                                                \def\bbl@elt##1##2##3##4{}%
                                                              \fi}%
188
                                           \bbl@languages
189
190\fi
```

6.4 Language options

Languages are loaded when processing the corresponding option except if a main language has been set. In such a case, it is not loaded until all options has been processed. The following macro inputs the ldf file and does some additional checks (\input works, too, but possible errors are not catched).

```
191 \let\bbl@afterlang\relax
192 \let\BabelModifiers\relax
193 \let\bbl@loaded\@empty
194 \def\bbl@load@language#1{%
    \InputIfFileExists{#1.ldf}%
       {\edef\bbl@loaded{\CurrentOption
196
197
          \ifx\bbl@loaded\@empty\else,\bbl@loaded\fi}%
198
        \expandafter\let\expandafter\bbl@afterlang
           \csname\CurrentOption.ldf-h@@k\endcsname
199
        \expandafter\let\expandafter\BabelModifiers
200
           \csname bbl@mod@\CurrentOption\endcsname}%
201
202
       {\bbl@error{%
203
          Unknown option '\CurrentOption'. Either you misspelled it\\%
          or the language definition file \CurrentOption.ldf was not found}{%
204
          Valid options are: shorthands=, KeepShorthandsActive,\\%
205
          activeacute, activegrave, noconfigs, safe=, main=, math=\\%
206
          headfoot=, strings=, config=, hyphenmap=, or a language name.}}}
Now, we set language options whose names are different from ldf files.
208 \DeclareOption{acadian}{\bbl@load@language{frenchb}}
209 \DeclareOption{afrikaans}{\bbl@load@language{dutch}}
210 \DeclareOption{american}{\bbl@load@language{english}}
211 \DeclareOption{australian}{\bbl@load@language{english}}
212 \DeclareOption{bahasa}{\bbl@load@language{bahasai}}

241 \DeclareOption{uppersorbian}{\bbl@load@language{usorbian}}
242 \DeclareOption{USenglish}{\bbl@load@language{english}}
```

Another way to extend the list of 'known' options for babel is to create the file bblopts.cfg in which one can add option declarations. However, this mechanism is deprecated – if you want an alternative name for a language, just create a new .ldf file loading the actual one. You can also set the name of the file with the package option config=<name>, which will load <name>.cfg instead.

```
243 \ifx\bbl@opt@config\@nnil
   \@ifpackagewith{babel}{noconfigs}{}%
     {\InputIfFileExists{bblopts.cfg}%
245
       246
247
               * Local config file bblopts.cfg used^^J%
248
              *}}%
249
       {}}%
250 \else
251
    \InputIfFileExists{\bbl@opt@config.cfg}%
252
     * Local config file \bbl@opt@config.cfg used^^J%
253
254
             *}}%
     {\bbl@error{%
255
256
        Local config file '\bbl@opt@config.cfg' not found}{%
        Perhaps you misspelled it.}}%
257
258 \fi
```

Recognizing global options in packages not having a closed set of them is not trivial, as for them to be processed they must be defined explicitly. So, package options not yet taken into account and stored in bbl@language@opts are assumed to be languages (note this list also contains the language given with main). If not declared above, the name of the option and the file are the same.

```
259 \bbl@for\bbl@tempa\bbl@language@opts{%
260 \@ifundefined{ds@\bbl@tempa}%
261 {\edef\bbl@tempb{%
262 \noexpand\DeclareOption
263 {\bbl@tempa}%
264 {\noexpand\bbl@load@language{\bbl@tempa}}}%
```

```
265 \bbl@tempb}%
266 \@empty}
```

281 \fi

Now, we make sure an option is explicitly declared for any language set as global option, by checking if an ldf exists. The previous step was, in fact, somewhat redundant, but that way we minimize accessing the file system just to see if the option could be a language.

```
267 \verb|\bbl@for\bbl@tempa\@classoptionslist{\%}|
     \@ifundefined{ds@\bbl@tempa}%
       {\IfFileExists{\bbl@tempa.ldf}%
269
         {\edef\bbl@tempb{%
270
            \noexpand\DeclareOption
271
              {\bbl@tempa}%
272
273
              {\noexpand\bbl@load@language{\bbl@tempa}}}%
274
          \bbl@tempb}%
275

276
       \@empty}
If a main language has been set, store it for the third pass.
277 \ifx\bbl@opt@main\@nnil\else
    \expandafter
     \let\expandafter\bbl@loadmain\csname ds@\bbl@opt@main\endcsname
     \DeclareOption{\bbl@opt@main}{}
```

And we are done, because all options for this pass has been declared. Those already processed in the first pass are just ignored.

The options have to be processed in the order in which the user specified them (except, of course, global options, which LATEX processes before):

```
282 \def\AfterBabelLanguage#1{%
283 \bbl@ifsamestring\CurrentOption{#1}{\global\bbl@add\bbl@afterlang}{}}
284 \DeclareOption*{}
285 \ProcessOptions*
```

This finished the second pass. Now the third one begins, which loads the main language set with the key main. A warning is raised if the main language is not the same as the last named one, or if the value of the key main is not a language. Then execute directly the option (because it could be used only in main). After loading all languages, we deactivate \AfterBabelLanguage.

```

```

7 The kernel of Babel (common)

The kernel of the babel system is stored in either hyphen.cfg or switch.def and babel.def. The file babel.def contains most of the code, while switch.def defines the language switching commands; both can be read at run time. The file hyphen.cfg is a file that can be loaded into the format, which is necessary when you want to be able to switch hyphenation patterns (by default, it also inputs switch.def, for "historical reasons", but it is not necessary). When babel.def is loaded it checks if the current version of switch.def is in the format; if not it is loaded. A further file, babel.sty, contains LATEX-specific stuff.

Because plain $T_E X$ users might want to use some of the features of the babel system too, care has to be taken that plain $T_E X$ can process the files. For this reason the current format will have to be checked in a number of places. Some of the code below is common to plain $T_E X$ and $I A T_E X$, some of it is for the $I A T_E X$ case only.

Plain formats based on etex (etex, xetex, luatex) don't load hyphen.cfg but etex.src, which follows a different naming convention, so we need to define the babel names. It presumes language.def exists and it is the same file used when formats were created.

7.1 Tools

\bbl@engine takes the following values: 0 is $pdfT_EX$, 1 is luatex, and 2 is xetex. You may use it in your language style if necessary.

\bbl@afterfi

\bbl@afterelse Because the code that is used in the handling of active characters may need to look ahead, we take extra care to 'throw' it over the \else and \fi parts of an \if-statement²⁵. These macros will break if another \if...\fi statement appears in one of the arguments and it is not enclosed in braces.

```
364 \long\def\bbl@afterelse#1\else#2\fi{\fi#1}
365 \long\def\bbl@afterfi#1\fi{\fi#1}
```

\addto For each language four control sequences have to be defined that control the language-specific definitions. To be able to add something to these macro once they have been defined the macro \addto is introduced. It takes two arguments, a $\langle control \ sequence \rangle$ and T_EX-code to be added to the $\langle control \ sequence \rangle$. If the (control sequence) has not been defined before it is defined now. The control sequence could also expand to \relax, in which case a circular definition results. The net result is a stack overflow. Otherwise the replacement text for the $\langle control$ sequence) is expanded and stored in a token register, together with the TFX-code

 $^{^{25}}$ This code is based on code presented in TUGboat vol. 12, no2, June 1991 in "An expansion Power" Lemma" by Sonja Maus.

to be added. Finally the (control sequence) is redefined, using the contents of the token register.

```
366 \def\addto#1#2{%
    \ifx#1\@undefined
       \def#1{#2}%
368
369
    \else
       \ifx#1\relax
         \def#1{#2}%
371
372
       \else
         {\toks@\expandafter{#1#2}%
373
374
          \xdef#1{\theta\times0}}%
375
       \fi
    \fi}
376
```

The macro \initiate@active@char takes all the necessary actions to make its argument a shorthand character. The real work is performed once for each character.

```
377 \def\bbl@withactive#1#2{%
    \begingroup
378
       \lccode'~='#2\relax
       \lowercase{\endgroup#1~}}
380
```

\bbl@redefine

To redefine a command, we save the old meaning of the macro. Then we redefine it to call the original macro with the 'sanitized' argument. The reason why we do it this way is that we don't want to redefine the LATEX macros completely in case their definitions change (they have changed in the past).

Because we need to redefine a number of commands we define the command \bbl@redefine which takes care of this. It creates a new control sequence, \org@...

```
381 \def\bbl@redefine#1{%
    \edef\bbl@tempa{\expandafter\@gobble\string#1}%
    \expandafter\let\csname org@\bbl@tempa\endcsname#1%
    \expandafter\def\csname\bbl@tempa\endcsname}
```

This command should only be used in the preamble of the document.

385 \@onlypreamble\bbl@redefine

\bbl@redefine@long

This version of \babel@redefine can be used to redefine \long commands such as \ifthenelse.

```
386 \def\bbl@redefine@long#1{%
    \edef\bbl@tempa{\expandafter\@gobble\string#1}%
    \expandafter\let\csname org@\bbl@tempa\endcsname#1%
    \expandafter\long\expandafter\def\csname\bbl@tempa\endcsname}
390 \@onlypreamble\bbl@redefine@long
```

\bbl@redefinerobust For commands that are redefined, but which might be robust we need a slightly more intelligent macro. A robust command foo is defined to expand to \protect\foo_. So it is necessary to check whether \foo_ exists. The result is that the command that is being redefined is always robust afterwards. Therefore all we need to do now is define \foo...

```
391 \def\bbl@redefinerobust#1{%
    \edef\bbl@tempa{\expandafter\@gobble\string#1}%
393
    \expandafter\ifx\csname\bbl@tempa\space\endcsname\relax
      \expandafter\let\csname org@\bbl@tempa\endcsname#1%
394
```

```
395 \expandafter\edef\csname\bbl@tempa\endcsname{\noexpand\protect
396 \expandafter\noexpand\csname\bbl@tempa\space\endcsname}%
397 \else
398 \expandafter\let\csname org@\bbl@tempa\expandafter\endcsname
399 \csname\bbl@tempa\space\endcsname
400 \fi
401 \expandafter\def\csname\bbl@tempa\space\endcsname}
```

This command should only be used in the preamble of the document. 402 \@onlypreamble\bbl@redefinerobust

7.2 Hooks

Note they are loaded in babel.def. switch.def only provides a "hook" for hooks (with a default value which is a no-op, below). Admittedly, the current implementation is a somewhat simplistic and does vety little to catch errors, but it is intended for developpers, after all. \bbl@usehooks is the commands used by babel to execute hooks defined for an event.

```
403 \def\AddBabelHook#1#2{%
   405
   \expandafter\bbl@tempa\bbl@evargs,#2=,\@empty
406
   \@ifundefined{bbl@ev@#1@#2}%
407
408
     {\bbl@csarg\bbl@add{ev@#2}{\bbl@elt{#1}}%
409
      \bbl@csarg\newcommand}%
     {\bbl@csarg\let{ev@#1@#2}\relax
410
411
      \bbl@csarg\newcommand}%
   {ev@#1@#2}[\bbl@tempb]}
413 \def\EnableBabelHook#1{\bbl@csarg\let{hk@#1}\@firstofone}
414 \def\DisableBabelHook#1{\bbl@csarg\let{hk@#1}\@gobble}
415 \def\bbl@usehooks#1#2{%
   \def\bbl@elt##1{%
416
417
     \@nameuse{bbl@ev@#1}}
```

To ensure forward compatibility, arguments in hooks are set implicitly. So, if a further argument is added in the future, there is no need to change the existing code. Note events intended for hyphen.cfg are also loaded (just in case you need them for some reason).

```
419 \def\bbl@evargs{,% don't delete the comma
420 everylanguage=1,loadkernel=1,loadpatterns=1,loadexceptions=1,%
421 adddialect=2,patterns=2,defaultcommands=0,encodedcommands=2,write=0,%
422 beforeextras=0,afterextras=0,stopcommands=0,stringprocess=0,%
423 hyphenation=2,initiateactive=3,afterreset=0}
```

\babelensure

The user command just parses the optional argument and creates a new macro named $\bdotbleense(\anguage)$. We register a hook at the afterextras event which just executes this macro in a "complete" selection (which, if undefined, is $\angle end on thing$). This part is somewhat involved because we have to make sure things are expanded the correct number of times.

The macro \bbl@ens@(language) contains

\bbl@ensure $\{\langle include \rangle\}\{\langle exclude \rangle\}\{\langle fontenc \rangle\}$, which in turn loops over the macros names in \bbl@ensured, excluding (with the help of \in@) those in the exclude list. If the fontenc is given (and not \relax), the \fontencoding is also added. Then we loop over the include list, but if the macro already contains

\foreignlanguage, nothing is done. Note this macro (1) is not restricted to the preamble, and (2) changes are local.

\bbl@ensured is the list of macros supposed to be "ensured".

```
424 \newcommand\babelensure[2][]{%
     \AddBabelHook{babel-ensure}{afterextras}{%

7.3 Setting up language files

\LdfInit

The second version of \LdfInit macro takes two arguments. The first argument is the name of the language that will be defined in the language definition file; the second argument is either a control sequence or a string from which a control sequence should be constructed. The existence of the control sequence indicates that the file has been processed before.

At the start of processing a language definition file we always check the category code of the at-sign. We make sure that it is a 'letter' during the processing of the file. We also save its name as the last called option, even if not loaded.

Another character that needs to have the correct category code during processing of language definition files is the equals sign, '=', because it is sometimes used in constructions with the \let primitive. Therefore we store its current catcode and restore it later on.

Now we check whether we should perhaps stop the processing of this file. To do this we first need to check whether the second argument that is passed to \LdfInit is a control sequence. We do that by looking at the first token after passing #2 through string. When it is equal to \@backslashchar we are dealing with a control sequence which we can compare with \@undefined.

If so, we call \ldf@quit to set the main language, restore the category code of the @-sign and call \endinput

When #2 was *not* a control sequence we construct one and compare it with \relax. Finally we check \originalTeX.

```
484 \def\LdfInit#1#2{%
    \chardef\atcatcode=\catcode'\@
485
486
     \catcode'\@=11\relax

\ldf@quit This macro interrupts the processing of a language definition file.

508 \def\ldf@quit#1{%

- 509 \expandafter\main@language\expandafter{#1}%
- \catcode'\@=\atcatcode \let\atcatcode\relax
- 511 \catcode'\==\eqcatcode \let\eqcatcode\relax
- 512 \endinput}

\ldf@finish This macro takes one argument. It is the name of the language that was defined in the language definition file.

We load the local configuration file if one is present, we set the main language (taking into account that the argument might be a control sequence that needs to be expanded) and reset the category code of the @-sign.

```
513 \def\ldf@finish#1{%
514 \loadlocalcfg{#1}%
```

- 515 \bbl@afterlang
- 516 \let\bbl@afterlang\relax

- \catcode'\@=\atcatcode \let\atcatcode\relax
- 521 \catcode'\==\eqcatcode \let\eqcatcode\relax}

After the preamble of the document the commands \LdfInit, \ldf@quit and \ldf@finish are no longer needed. Therefore they are turned into warning messages in LATEX.

```
522 \@onlypreamble\LdfInit
```

523 \@onlypreamble\ldf@quit

524 \@onlypreamble\ldf@finish

\main@language \bbl@main@language

This command should be used in the various language definition files. It stores its argument in \bbl@main@language; to be used to switch to the correct language at the beginning of the document.

```
525 \def\main@language#1{%
```

- 526 \def\bbl@main@language{#1}%
- 527 \let\languagename\bbl@main@language
- 528 \bbl@patterns{\languagename}}

We also have to make sure that some code gets executed at the beginning of the document.

```
529 \AtBeginDocument {%
```

\expandafter\selectlanguage\expandafter{\bbl@main@language}}

7.4 Shorthands

\bbl@add@special

The macro \bbl@add@special is used to add a new character (or single character control sequence) to the macro \dospecials (and \@sanitize if L^TEX is used). To keep all changes local, we begin a new group. Then we redefine the macros \do and \@makeother to add themselves and the given character without expansion. To add the character to the macros, we expand the original macros with the additional character inside the redefinition of the macros. Because \@sanitize can be undefined, we put the definition inside a conditional.

```
531 \def\bbl@add@special#1{%
     \begingroup
       \def\do{\noexpand\do\noexpand}%
533
       \def\@makeother{\noexpand\@makeother\noexpand}%
534
535
     \edef\x{\endgroup
       \def\noexpand\dospecials{\dospecials\do#1}%
536
       \expandafter\ifx\csname @sanitize\endcsname\relax \else
537
538
         \def\noexpand\@sanitize{\@sanitize\@makeother#1}%
       \fi}%
539
540
    \x
```

The macro \x contains at this moment the following:

 $\end{group} \def\dospecials {old\ contents\ \do\langle char\rangle}.$

If $\ensuremath{\mbox{\sc Manitize}}$ is defined, it contains an additional definition of this macro. The last thing we have to do, is the expansion of $\xspace x$. Then $\mbox{\sc Manitize}$ is executed, which restores the old meaning of $\xspace x$, $\sc Manitize$ and $\sc Manitize$ is assigned.

\bbl@remove@special

The companion of the former macro is \bbl@remove@special. It is used to remove a character from the set macros \dospecials and \@sanitize.

To keep all changes local, we begin a new group. Then we define a help macro \x , which expands to empty if the characters match, otherwise it expands to its nonexpandable input. Because $\xspace{T_EX}$ inserts a $\xspace{T_EX}$ in the corresponding $\xspace{T_EX}$ is scanned before the comparison is evaluated, we provide a 'stop sign' which should expand to nothing.

With the help of this macro we define \do and \make@other.

The rest of the work is similar to \bbl@add@special.

```
541 \def\bbl@remove@special#1{%

         \def\noexpand\@sanitize{\@sanitize}%
550
551
       \fi}%
     \x}
```

\initiate@active@char

A language definition file can call this macro to make a character active. This macro takes one argument, the character that is to be made active. When the character was already active this macro does nothing. Otherwise, this macro defines the control sequence $\normal@char\langle char\rangle$ to expand to the character in its 'normal state' and it defines the active character to expand to $\normal@char\langle char\rangle$ by default ($\normal@char\langle char\rangle$ being the character to be made active). Later its definition can be changed to expand to $\active@char\langle char\rangle$ by calling $\begin{align*} bbl@activate\{\langle char\rangle\}. \\ For example, to make the double quote character active one could have <math>\alpha$ in a language definition file. This defines "as $\active@char\{"\}$ in a language definition file. This defines "as $\active@char\{"\}$ in a cative@char" (where the first " is the character with its original catcode, when the shorthand is created, and $\active@char"$ is a single token). In protected contexts, it expands to $\active@char"$ is executed. This macro in turn expands to $\active@char"$ in "safe" contexts (eg, $\active@char"$ in normal

"unsafe" ones. The latter search a definition in the user, language and system levels, in this order, but if none is found, \normal@char" is used. However, a deactivated shorthand (with \bbl@deactivate is defined as \active@prefix "\normal@char".

The following macro is used to define shorthands in the three levels. It takes 4 arguments: the (string'ed) character, \<level>@group, <level>@active and <next-level>@active (except in system).

```
553 \def\bbl@active@def#1#2#3#4{%
554 \@namedef{#3#1}{%
555 \expandafter\ifx\csname#2@sh@#1@\endcsname\relax
556 \bbl@afterelse\bbl@sh@select#2#1{#3@arg#1}{#4#1}%
557 \else
558 \bbl@afterfi\csname#2@sh@#1@\endcsname
559 \fi}%
```

When there is also no current-level shorthand with an argument we will check whether there is a next-level defined shorthand for this active character.

```
\long\@namedef{#3@arg#1}##1{%
\expandafter\ifx\csname#2@sh@#1@\string##1@\endcsname\relax
\bbl@afterelse\csname#4#1\endcsname##1%
\else
\bbl@afterfi\csname#2@sh@#1@\string##1@\endcsname
\fi}}%
```

\initiate@active@char calls \@initiate@active@char with 3 arguments. All of them are the same character with different catcodes: active, other (string'ed) and the original one.

```
566 \def\initiate@active@char#1{%
567 \expandafter\ifx\csname active@char\string#1\endcsname\relax
568 \bbl@withactive
569 {\expandafter\@initiate@active@char\expandafter}#1\string#1#1%
570 \fi}
```

The very first thing to do is saving the original catcode and the original definition, even if not active, which is possible (undefined characters require a special treatement to avoid making them \relax).

```
571 \def\@initiate@active@char#1#2#3{%
    \expandafter\edef\csname bbl@oricat@#2\endcsname{%
572
       \catcode'#2=\the\catcode'#2\relax}%
573
    \ifx#1\@undefined
       \expandafter\edef\csname bbl@oridef@#2\endcsname{%
575
576
         \let\noexpand#1\noexpand\@undefined}%
577
       \expandafter\let\csname bbl@oridef@@#2\endcsname#1%
578
       \expandafter\edef\csname bbl@oridef@#2\endcsname{%
579
580
         \let\noexpand#1%
         \expandafter\noexpand\csname bbl@oridef@@#2\endcsname}%
581
    \fi
582
```

If the character is already active we provide the default expansion under this shorthand mechanism. Otherwise we write a message in the transcript file, and define $\normal@char(char)$ to expand to the character in its default state. If the character is mathematically active when babel is loaded (for example ') the normal expansion is somewhat different to avoid an infinite loop (but it does not prevent the loop if the mathcode is set to "8000 a posteriori).

```
583 \ifx#1#3\relax
```

```
\expandafter\let\csname normal@char#2\endcsname#3%
\else
\bbl@info{Making #2 an active character}%
\ifnum\mathcode'#2="8000
\@namedef{normal@char#2}{%
\textormath{#3}{\csname bbl@oridef@@#2\endcsname}}%
\else
\@namedef{normal@char#2}{#3}%
\fi
```

To prevent problems with the loading of other packages after babel we reset the catcode of the character to the original one at the end of the package and of each language file (except with KeepShorthandsActive). It is re-activate again at \begin{document}. We also need to make sure that the shorthands are active during the processing of the .aux file. Otherwise some citations may give unexpected results in the printout when a shorthand was used in the optional argument of \bibitem for example. Then we make it active (not strictly necessary, but done for backward compatibility).

```
593 \bbl@restoreactive{#2}%
594 \AtBeginDocument{%
595 \catcode'#2\active
596 \if@filesw
597 \immediate\write\@mainaux{\catcode'\string#2\active}%
598 \fi}%
599 \expandafter\bbl@add@special\csname#2\endcsname
600 \catcode'#2\active
601 \fi
```

Now we have set \normal@char\char\, we must define \active@char\char\, to be executed when the character is activated. We define the first level expansion of \active@char\char\ to check the status of the @safe@actives flag. If it is set to true we expand to the 'normal' version of this character, otherwise we call \user@active\char\ to start the search of a definition in the user, language and system levels (or eventually normal@char\char\char\).

```
\let\bbl@tempa\@firstoftwo
     \if\string^#2%
603
604
       \def\bbl@tempa{\noexpand\textormath}%
605
       \ifx\bbl@mathnormal\@undefined\else
606
607
         \let\bbl@tempa\bbl@mathnormal
608
    \fi
609
     \expandafter\edef\csname active@char#2\endcsname{%
610
       \bbl@tempa
611
         {\noexpand\if@safe@actives
612
613
            \noexpand\expandafter
            \expandafter\noexpand\csname normal@char#2\endcsname
614
615
          \noexpand\else
616
            \noexpand\expandafter
            \expandafter\noexpand\csname bbl@doactive#2\endcsname
617
618
          \noexpand\fi}%
        {\expandafter\noexpand\csname normal@char#2\endcsname}}%
619
620
     \bbl@csarg\edef{doactive#2}{%
       \expandafter\noexpand\csname user@active#2\endcsname}%
```

We now define the default values which the shorthand is set to when activated or

deactivated. It is set to the deactivated form (globally), so that the character expands to

```
\active@prefix \langle char \rangle \normal@char\langle char \rangle
```

(where \active@char $\langle char \rangle$ is one control sequence!).

```
\bbl@csarg\edef{active@#2}{%
       \noexpand\active@prefix\noexpand#1%
623
       \expandafter\noexpand\csname active@char#2\endcsname}%
624
    \bbl@csarg\edef{normal@#2}{%
625
626
       \noexpand\active@prefix\noexpand#1%
       \expandafter\noexpand\csname normal@char#2\endcsname}%
627
628
    \expandafter\let\expandafter#1\csname bbl@normal@#2\endcsname
```

The next level of the code checks whether a user has defined a shorthand for himself with this character. First we check for a single character shorthand. If that doesn't exist we check for a shorthand with an argument.

```
\bbl@active@def#2\user@group{user@active}{language@active}%
630
    \bbl@active@def#2\language@group{language@active}{system@active}%
    \bbl@active@def#2\system@group{system@active}{normal@char}%
```

In order to do the right thing when a shorthand with an argument is used by itself at the end of the line we provide a definition for the case of an empty argument. For that case we let the shorthand character expand to its non-active self. Also, When a shorthand combination such as '' ends up in a heading TFX would see \protect'\protect'. To prevent this from happening a couple of shorthand needs to be defined at user level.

```
\expandafter\edef\csname\user@group @sh@#2@@\endcsname
633
       {\expandafter\noexpand\csname normal@char#2\endcsname}%
    \expandafter\edef\csname\user@group @sh@#2@\string\protect@\endcsname
634
       {\expandafter\noexpand\csname user@active#2\endcsname}%
```

Finally, a couple of special cases are taken care of. (1) If we are making the right quote (') active we need to change \pr@m@s as well. Also, make sure that a single ' in math mode 'does the right thing'. (2) If we are using the caret (^) as a shorthand character special care should be taken to make sure math still works. Therefore an extra level of expansion is introduced with a check for math mode on the upper level.

```
\if\string'#2%
       \let\prim@s\bbl@prim@s
637
       \let\active@math@prime#1%
638
639
    \bbl@usehooks{initiateactive}{{#1}{#2}{#3}}}
640
```

The following package options control the behaviour of shorthands in math mode.

```
641 \langle \langle *More package options \rangle \rangle \equiv
642 \DeclareOption{math=active}{}
643 \verb|\DeclareOption{math=normal}{\def\bbl@mathnormal{\noexpand\textormath}}|
644 ((/More package options))
```

Initiating a shorthand makes active the char. That is not strictly necessary but it is still done for backward compatibility. So we need to restore the original catcode at the end of package and and the end of the ldf.

```
645 \@ifpackagewith{babel}{KeepShorthandsActive}%
    {\let\bbl@restoreactive\@gobble}%
    {\def\bbl@restoreactive#1{%
```

```
\edef\bbl@tempa{%
648
          \noexpand\AfterBabelLanguage\noexpand\CurrentOption
649
            {\catcode'#1=\the\catcode'#1\relax}%
650
          \noexpand\AtEndOfPackage{\catcode'#1=\the\catcode'#1\relax}}%
651
        \bbl@tempa}%
652
      \AtEndOfPackage{\let\bbl@restoreactive\@gobble}}
653
```

\bbl@select This command helps the shorthand supporting macros to select how to proceed. Note that this macro needs to be expandable as do all the shorthand macros in order for them to work in expansion-only environments such as the argument of \hyphenation.

> This macro expects the name of a group of shorthands in its first argument and a shorthand character in its second argument. It will expand to either \bbl@firstcs or \bbl@scndcs. Hence two more arguments need to follow it.

```
654 \def\bbl@sh@select#1#2{%
    \expandafter\ifx\csname#1@sh@#2@sel\endcsname\relax
       \bbl@afterelse\bbl@scndcs
656
657
     \else
       \bbl@afterfi\csname#1@sh@#2@sel\endcsname
658
659
    \fi}
```

\active@prefix The command \active@prefix which is used in the expansion of active characters has a function similar to \OT1-cmd in that it \protects the active character whenever \protect is not \@typeset@protect.

```
660 \def\active@prefix#1{%
    \ifx\protect\@typeset@protect
662
    \else
```

When \protect is set to \@unexpandable@protect we make sure that the active character is als *not* expanded by inserting \noexpand in front of it. The \@gobble is needed to remove a token such as \activechar: (when the double colon was the active character to be dealt with).

```
\ifx\protect\@unexpandable@protect
664
         \noexpand#1%
665
       \else
         \protect#1%
666
667
       \expandafter\@gobble
668
     \fi}
```

\if@safe@actives In some circumstances it is necessary to be able to change the expansion of an active character on the fly. For this purpose the switch @safe@actives is available. The setting of this switch should be checked in the first level expansion of \active@char $\langle char \rangle$.

```
670 \newif\if@safe@actives
671 \@safe@activesfalse
```

\bbl@restore@actives When the output routine kicks in while the active characters were made "safe" this must be undone in the headers to prevent unexpected typeset results. For this situation we define a command to make them "unsafe" again.

```
672 \def\bbl@restore@actives{\if@safe@actives\@safe@activesfalse\fi}
```

\bbl@activate Both macros take one argument, like \initiate@active@char. The macro is used \bbl@deactivate to change the definition of an active character to expand to \active@char $\langle char \rangle$ in the case of \bbl@activate, or \normal@char $\langle char \rangle$ in the case of \bbl@deactivate.

```
673 \def\bbl@activate#1{%
    \bbl@withactive{\expandafter\let\expandafter}#1%
      \csname bbl@active@\string#1\endcsname}
676 \def\bbl@deactivate#1{%
    \bbl@withactive{\expandafter\let\expandafter}#1%
      \csname bbl@normal@\string#1\endcsname}
```

\bbl@firstcs These macros have two arguments. They use one of their arguments to build a \bbl@scndcs control sequence from.

```
679 \def\bbl@firstcs#1#2{\csname#1\endcsname}
680 \def\bbl@scndcs#1#2{\csname#2\endcsname}
```

\declare@shorthand

The command \declare@shorthand is used to declare a shorthand on a certain level. It takes three arguments:

- 1. a name for the collection of shorthands, i.e. 'system', or 'dutch';
- 2. the character (sequence) that makes up the shorthand, i.e. ~ or "a;
- 3. the code to be executed when the shorthand is encountered.

```
681 \def\declare@shorthand#1#2{\@decl@short{#1}#2\@nil}
682 \ensuremath{\mbox{def}\ensuremath{\mbox{@decl@short}#1\#2\#3}\ensuremath{\mbox{@nil}\#4\{\%\}}}
                          \def\bbl@tempa{#3}%
684
                            \ifx\bbl@tempa\@empty

                                                          \fi}%
705
                                        \ensuremath{\mbox{\mbox{0}}} \ensuremath{\mbox{0}} \ensuremath{\
                            \fi}
```

\textormath Some of the shorthands that will be declared by the language definition files have to be usable in both text and mathmode. To achieve this the helper macro \textormath is provided.

```
707 \def\textormath{%
708
    \ifmmode
       \expandafter\@secondoftwo
709
710
    \else
```

```
711
       \expandafter\@firstoftwo
712
     \fi}
```

\user@group \language@group \system@group

The current concept of 'shorthands' supports three levels or groups of shorthands. For each level the name of the level or group is stored in a macro. The default is to have a user group; use language group 'english' and have a system group called 'system'.

```
713 \def\user@group{user}
714 \def\language@group{english}
715 \def\system@group{system}
```

\useshorthands This is the user level command to tell IATFX that user level shorthands will be used in the document. It takes one argument, the character that starts a shorthand. First note that this is user level, and then initialize and activate the character for use as a shorthand character (ie, it's active in the preamble). Languages can deactivate shorthands, so a starred version is also provided which activates them always after the language has been switched.

```
716 \def\useshorthands{%
    \@ifstar\bbl@usesh@s{\bbl@usesh@x{}}}
718 \def\bbl@usesh@s#1{%
    \bbl@usesh@x
       {\AddBabelHook{babel-sh-\string#1}{afterextras}{\bbl@activate{#1}}}%
721
       {#1}}
722 \def\bbl@usesh@x#1#2{%
    \bbl@ifshorthand{#2}%
       {\def\user@group{user}%
724
725
        \initiate@active@char{#2}%
726
        \bbl@activate{#2}}%
727
       {\bbl@error
          {Cannot declare a shorthand turned off (\string#2)}
729
          {Sorry, but you cannot use shorthands which have been\\%
730
           turned off in the package options}}}
```

\defineshorthand Currently we only support two groups of user level shorthands, named internally user and user@<lang> (language-dependent user shorthands). By default, only the first one is taken into account, but if the former is also used (in the optional argument of \defineshorthand) a new level is inserted for it (user@generic, done by \bbl@set@user@generic); we make also sure {} and \protect are taken into account in this new top level.

```
732 \def\user@language@group{user@\language@group}
733 \def\bbl@set@user@generic#1#2{%
    \@ifundefined{user@generic@active#1}%
       {\bbl@active@def#1\user@language@group{user@active}{user@generic@active}%
       \bbl@active@def#1\user@group{user@generic@active}{language@active}%
736
737
        \expandafter\edef\csname#2@sh@#1@@\endcsname{%
          \expandafter\noexpand\csname normal@char#1\endcsname}%
738
        \expandafter\edef\csname#2@sh@#1@\string\protect@\endcsname{%
739
740
          \expandafter\noexpand\csname user@active#1\endcsname}}%
741
    \@empty}
742 \newcommand\defineshorthand[3][user]{%
    \edef\bbl@tempa{\zap@space#1 \@empty}%
    \bbl@for\bbl@tempb\bbl@tempa{%
744
      \if*\expandafter\@car\bbl@tempb\@nil
745

746
```

```
\@expandtwoargs
747
           \bbl@set@user@generic{\expandafter\string\@car#2\@nil}\bbl@tempb
748
       \fi
749
       \declare@shorthand{\bbl@tempb}{#2}{#3}}}
750
```

\languageshorthands A user level command to change the language from which shorthands are used. Unfortunately, babel currently does not keep track of defined groups, and therefore there is no way to catch a possible change in casing.

751 \def\languageshorthands#1{\def\language@group{#1}}

\aliasshorthand First the new shorthand needs to be initialized,

```
752 \def\aliasshorthand#1#2{%
    \bbl@ifshorthand{#2}%
754
       {\expandafter\ifx\csname active@char\string#2\endcsname\relax
          \ifx\document\@notprerr
755
            \@notshorthand{#2}%
756
          \else
757
            \initiate@active@char{#2}%
758
```

Then, we define the new shorthand in terms of the original one, but note with \aliasshorthands{"}{/} is \active@prefix /\active@char/, so we still need to let the lattest to \active@char".

```
\expandafter\let\csname active@char\string#2\expandafter\endcsname
759
760
              \csname active@char\string#1\endcsname
761
            \expandafter\let\csname normal@char\string#2\expandafter\endcsname
              \csname normal@char\string#1\endcsname
762
763
            \bbl@activate{#2}%
764
          \fi
765
        \fi}%
766
       {\bbl@error
          {Cannot declare a shorthand turned off (\string#2)}
767
768
          {Sorry, but you cannot use shorthands which have been\\%
           turned off in the package options}}}
769
```

\@notshorthand

```
770 \def\@notshorthand#1{%
    \bbl@error{%
       The character '\string #1' should be made a shorthand character;\\%
772
773

774
       the preamble.\\%
       I will ignore your instruction}%
775
      {You may proceed, but expect unexpected results}}
776
```

\shorthandon \shorthandoff

The first level definition of these macros just passes the argument on to \bbl@switch@sh, adding \@nil at the end to denote the end of the list of characters.

```
777 \newcommand*\shorthandon[1] {\bbl@switch@sh\@ne#1\@nnil}
778 \DeclareRobustCommand*\shorthandoff{%
779 \@ifstar{\bbl@shorthandoff\tw@}{\bbl@shorthandoff\z@}}
780 \def\bbl@shorthandoff#1#2{\bbl@switch@sh#1#2\@nnil}
```

\bbl@switch@sh

The macro \bbl@switch@sh takes the list of characters apart one by one and subsequently switches the category code of the shorthand character according to the first argument of \bbl@switch@sh.

But before any of this switching takes place we make sure that the character we are dealing with is known as a shorthand character. If it is, a macro such as \active@char" should exist.

Switching off and on is easy – we just set the category code to 'other' (12) and \active. With the starred version, the original catcode and the original definition, saved in @initiate@active@char, are restored.

```
781 \def\bbl@switch@sh#1#2{%
    \@ifundefined{bbl@active@\string#2}%
783
784

822 \fi
```

\bbl@prim@s One of the internal macros that are involved in substituting \prime for each right \bbl@pr@m@s quote in mathmode is \prim@s. This checks if the next character is a right quote.

When the right quote is active, the definition of this macro needs to be adapted to look also for an active right quote; the hat could be active, too.

```
823 \def\bbl@prim@s{%
    \prime\futurelet\@let@token\bbl@pr@m@s}
825 \def\bbl@if@primes#1#2{%
    \ifx#1\@let@token

      \bbl@afterelse\expandafter\@firstoftwo
830
    \else
      \bbl@afterfi\expandafter\@secondoftwo
831
    \fi\fi}
833 \begingroup
    \catcode'\^=7 \catcode'\*=\active \lccode'\*='\^
    \catcode'\'=12 \catcode'\"=\active \lccode'\"='\'
    \lowercase{%
836
      \gdef\bbl@pr@m@s{%
837
         \bbl@if@primes"'%
838
839
           \pr@@@s
           {\bbl@if@primes*^\pr@@@t\egroup}}}
840
841 \endgroup
```

Usually the \sim is active and expands to \penalty\@M\ $_$. When it is written to the . aux file it is written expanded. To prevent that and to be able to use the character ~ as a start character for a shorthand, it is redefined here as a one character shorthand on system level. The system declaration is in most cases redundant (when ~ is still a non-break space), and in some cases is inconvenient (if ~ has been redefined); however, for backward compatibility it is maintained (some existing documents may rely on the babel value).

```
842 \initiate@active@char{~}
843 \declare@shorthand{system}{~}{\leavevmode\nobreak\ }
844 \bbl@activate{~}
```

\T1dqpos

\0T1dqpos The position of the double quote character is different for the OT1 and T1 encodings. It will later be selected using the \f@encoding macro. Therefore we define two macros here to store the position of the character in these encodings.

```
845 \expandafter\def\csname OT1dqpos\endcsname{127}
846 \expandafter\def\csname Tldqpos\endcsname{4}
```

When the macro \f@encoding is undefined (as it is in plain T_FX) we define it here to expand to 0T1

```
847 \ifx\f@encoding\@undefined
848 \def\f@encoding{0T1}
849 \fi
```

7.5 Language attributes

Language attributes provide a means to give the user control over which features of the language definition files he wants to enable.

\languageattribute

The macro \languageattribute checks whether its arguments are valid and then activates the selected language attribute. First check whether the language is known, and then process each attribute in the list.

```
850 \newcommand\languageattribute[2]{%
851 \def\bbl@tempc{#1}%
```

```
852 \bbl@fixname\bbl@tempc
853 \bbl@iflanguage\bbl@tempc{%
854 \bbl@loopx\bbl@attr{#2}{%
```

We want to make sure that each attribute is selected only once; therefore we store the already selected attributes in \bbl@known@attribs. When that control sequence is not yet defined this attribute is certainly not selected before.

```
\ifx\bbl@known@attribs\@undefined
s56 \in@false
857 \else
```

Now we need to see if the attribute occurs in the list of already selected attributes.

```
% \@expandtwoargs\in@{,\bbl@tempc-\bbl@attr,}{,\bbl@known@attribs,}% \fi
```

When the attribute was in the list we issue a warning; this might not be the users intention

```
860 \ifin@
861 \bbl@warning{%
862 You have more than once selected the attribute '\bbl@attr'\\%
863 for language #1}%
864 \else
```

When we end up here the attribute is not selected before. So, we add it to the list of selected attributes and execute the associated T_EX -code.

```
\edef\bbl@tempa{%
865
866
             \noexpand\bbl@add@list
867
             \noexpand\bbl@known@attribs{\bbl@tempc-\bbl@attr}}%
           \bbl@tempa
868
           \edef\bbl@tempa{\bbl@tempc-\bbl@attr}%
869
           \expandafter\bbl@ifknown@ttrib\expandafter{\bbl@tempa}\bbl@attributes%
870
           {\csname\bbl@tempc @attr@\bbl@attr\endcsname}%
871
872
           {\@attrerr{\bbl@tempc}{\bbl@attr}}%
        \fi}}}
```

This command should only be used in the preamble of a document.

874 \@onlypreamble\languageattribute

The error text to be issued when an unknown attribute is selected.

```
875 \newcommand*{\@attrerr}[2]{%
876 \bbl@error
877 {The attribute #2 is unknown for language #1.}%
878 {Your command will be ignored, type <return> to proceed}}
```

\bbl@declare@ttribute

This command adds the new language/attribute combination to the list of known attributes.

Then it defines a control sequence to be executed when the attribute is used in a document. The result of this should be that the macro \extras... for the current language is extended, otherwise the attribute will not work as its code is removed from memory at \begin{document}.

```
879 \def\bbl@declare@ttribute#1#2#3{%
880 \@expandtwoargs\in@{,#2,}{,\BabelModifiers,}%
881 \ifin@
882 \AfterBabelLanguage{#1}{\languageattribute{#1}{#2}}%
883 \fi
884 \bbl@add@list\bbl@attributes{#1-#2}%
885 \expandafter\def\csname#1@attr@#2\endcsname{#3}}
```

\bbl@ifattributeset This internal macro has 4 arguments. It can be used to interpret TeX code based on whether a certain attribute was set. This command should appear inside the argument to \AtBeginDocument because the attributes are set in the document preamble, after babel is loaded.

> The first argument is the language, the second argument the attribute being checked, and the third and fourth arguments are the true and false clauses.

```
886 \def\bbl@ifattributeset#1#2#3#4{%
```

First we need to find out if any attributes were set; if not we're done.

```
\ifx\bbl@known@attribs\@undefined
       \in@false
888
    \else
889
```

The we need to check the list of known attributes.

```
\@expandtwoargs\in@{,#1-#2,}{,\bbl@known@attribs,}%
890
891
```

When we're this far \ifin@ has a value indicating if the attribute in question was set or not. Just to be safe the code to be executed is 'thrown over the \fi'.

```
\ifin@
       \bbl@afterelse#3%
893
894
     \else
895
       \bbl@afterfi#4%
896
     \fi
897
     }
```

\bbl@add@list This internal macro adds its second argument to a comma separated list in its first argument. When the list is not defined yet (or empty), it will be initiated

```
898 \def\bbl@add@list#1#2{%
     \ifx#1\@undefined
899
       \def#1{#2}%
900
901
     \else
902
       \ifx#1\@empty
903
         \def#1{#2}%
       \else
904
         \edef#1{#1,#2}%
905
       \fi
906
     \fi
907
908
     }
```

\bbl@ifknown@ttrib

An internal macro to check whether a given language/attribute is known. The macro takes 4 arguments, the language/attribute, the attribute list, the TFX-code to be executed when the attribute is known and the TFX-code to be executed otherwise.

```
909 \def\bbl@ifknown@ttrib#1#2{%
```

We first assume the attribute is unknown.

```
910 \let\bbl@tempa\@secondoftwo
```

Then we loop over the list of known attributes, trying to find a match.

```
\bbl@loopx\bbl@tempb{#2}{%
      \expandafter\in@\expandafter{\expandafter,\bbl@tempb,}{,#1,}%
912
      \ifin@
```

When a match is found the definition of \bbl@tempa is changed.

```
914
         \let\bbl@tempa\@firstoftwo
       \else
915
       \fi}%
916
```

```
Finally we execute \bbl@tempa.
                       \bbl@tempa
                   918 }
\bbl@clear@ttribs This macro removes all the attribute code from LATEX's memory at
                   \begin{document} time (if any is present).
                   919 \def\bbl@clear@ttribs{%
                       \ifx\bbl@attributes\@undefined\else
                          \bbl@loopx\bbl@tempa{\bbl@attributes}{%
                   921
                   922
                            \expandafter\bbl@clear@ttrib\bbl@tempa.
                   923
                            }%
                   924
                          \let\bbl@attributes\@undefined
                       \fi
                   925
                   926 }
                   927 \def\bbl@clear@ttrib#1-#2.{%
                       \expandafter\let\csname#1@attr@#2\endcsname\@undefined}
                   929 \AtBeginDocument{\bbl@clear@ttribs}
```

7.6 Support for saving macro definitions

To save the meaning of control sequences using \babel@save, we use temporary control sequences. To save hash table entries for these control sequences, we don't use the name of the control sequence to be saved to construct the temporary name. Instead we simply use the value of a counter, which is reset to zero each time we begin to save new values. This works well because we release the saved meanings before we begin to save a new set of control sequence meanings (see \selectlanguage and \originalTeX). Note undefined macros are not undefined any more when saved - they are \relax'ed.

\babel@savecnt The initialization of a new save cycle: reset the counter to zero.

 $\verb|\babel@beginsave| 930 \verb|\def| babel@beginsave{\babel@savecnt|z@}|$

Before it's forgotten, allocate the counter and initialize all.

```
931 \newcount\babel@savecnt
932 \babel@beginsave
```

\babel@save The macro \babel@save(csname) saves the current meaning of the control sequence $\langle csname \rangle$ to $\langle csname \rangle$ temporary control sequence, the restore commands are appended to \originalTeX and the counter is incremented.

```
933 \def\babel@save#1{%
    \expandafter\let\csname babel@\number\babel@savecnt\endcsname#1\relax
935
    \begingroup
936
       \toks@\expandafter{\originalTeX\let#1=}%
937
       \edef\x{\endgroup
         \def\noexpand\originalTeX{\the\toks@ \expandafter\noexpand
938
            \csname babel@\number\babel@savecnt\endcsname\relax}}%
939
940
    \x
    \advance\babel@savecnt\@ne}
```

\babel@savevariable The macro \babel@savevariable(variable) saves the value of the variable. (*variable*) can be anything allowed after the \the primitive.

942 \def\babel@savevariable#1{\begingroup

²⁶\originalTeX has to be expandable, i. e. you shouldn't let it to \relax.

```
943 \toks@\expandafter{\originalTeX #1=}%
944 \edef\x{\endgroup
945 \def\noexpand\originalTeX{\the\toks@ \the#1\relax}}%
946 \x}
```

\bbl@frenchspacing
\bbl@nonfrenchspacing

Some languages need to have \frenchspacing in effect. Others don't want that. The command \bbl@frenchspacing switches it on when it isn't already in effect and \bbl@nonfrenchspacing switches it off if necessary.

```
947 \def\bbl@frenchspacing{%
948 \ifnum\the\sfcode'\.=\@m
949 \let\bbl@nonfrenchspacing\relax
950 \else
951 \frenchspacing
952 \let\bbl@nonfrenchspacing\nonfrenchspacing
953 \fi}
954 \let\bbl@nonfrenchspacing\nonfrenchspacing
```

7.7 Short tags

\babeltags

This macro is straightforward. After zapping spaces, we loop over the list and define the macros $\text{text}\langle tag\rangle$ and $\text{tag}\rangle$. Definitions are first expanded so that they don't contain csname but the actual macro.

```
955 \def\babeltags#1{%
    \edef\bbl@tempa{\zap@space#1 \@empty}%
     \def\bbl@tempb##1=##2\@@{%

7.8 Hyphens

\babelhyphenation

This macro saves hyphenation exceptions. Two macros are used to store them: \bbl@hyphenation@ for the global ones and \bbl@hyphenation<lang> for language ones. See \bbl@patterns above for further details. We make sure there is a space between words when multiple commands are used.

```
969 \@onlypreamble\babelhyphenation
970 \AtEndOfPackage{%
    \newcommand\babelhyphenation[2][\@empty]{%
      \ifx\bbl@hyphenation@\relax
972
973
         \let\bbl@hyphenation@\@empty
       \fi
974
       \ifx\bbl@hyphlist\@empty\else
975
         \bbl@warning{%
976

991
               #2}}}%
992
993
       \fi}}
```

\bbl@allowhyphens

This macro makes hyphenation possible. Basically its definition is nothing more than \nobreak \hskip Opt plus Opt²⁷.

```
994 \def\bbl@allowhyphens{\ifvmode\else\nobreak\hskip\z@skip\fi}
995 \def\bbl@t@one{T1}
996 \def\allowhyphens{\ifx\cf@encoding\bbl@t@one\else\bbl@allowhyphens\fi}
```

\babelhyphen

Macros to insert common hyphens. Note the space before @ in \babelhyphen. Instead of protecting it with \DeclareRobustCommand, which could insert a \relax, we use the same procedure as shorthands.

```
997 \newcommand\babelnullhyphen{\char\hyphenchar\font}
998 \def\babelhyphen{\active@prefix\babelhyphen\bbl@hyphen}
999 \def\bbl@hyphen{%
1000 \@ifstar{\bbl@hyphen@i @}{\bbl@hyphen@i\@empty}}
1001 \def\bbl@hyphen@i#1#2{%
1002 \@ifundefined{bbl@hy@#1#2\@empty}%
1003 {\csname bbl@#1usehyphen\endcsname{\discretionary{#2}{}{#2}}}%
1004 {\csname bbl@hy@#1#2\@empty\endcsname}}
```

The following two commands are used to wrap the "hyphen" and set the behaviour of the rest of the word – the version with a single @ is used when further hyphenation is allowed, while that with @@ if no more hyphen are allowed. In both cases, if the hyphen is preceded by a positive space, breaking after the hyphen is disallowed.

There should not be a discretionaty after a hyphen at the beginning of a word, so it is prevented if preceded by a skip. Unfortunately, this does handle cases like "(-suffix)". \nobreak is always preceded by \leavevmode, in case the shorthand starts a paragraph.

```
1005 \def\bbl@usehyphen#1{%
1006 \leavevmode
1007 \ifdim\lastskip>\z@\mbox{#1}\nobreak\else\nobreak#1\fi
1008 \hskip\z@skip}
1009 \def\bbl@usehyphen#1{%
1010 \leavevmode\ifdim\lastskip>\z@\mbox{#1}\else#1\fi}
The following macro inserts the hyphen char.
1011 \def\bbl@hyphenchar{%
1012 \ifnum\hyphenchar\font=\m@ne
1013 \babelnullhyphen
```

 $^{^{27}\}text{TeX}$ begins and ends a word for hyphenation at a glue node. The penalty prevents a linebreak at this glue node.

```
\else
1014
       \char\hyphenchar\font
1015
1016
     \fi}
 Finally, we define the hyphen "types". Their names will not change, so you may
 use them in ldf's.

1031 \def\bbl@hy@@empty{\discretionary{}{}{}}
```

\bbl@disc For some languages the macro \bbl@disc is used to ease the insertion of discretionaries for letters that behave 'abnormally' at a breakpoint.

1032 \def\bbl@disc#1#2{\nobreak\discretionary{#2-}{}{#1}\bbl@allowhyphens}

7.9 Multiencoding strings

The aim following commands is to provide a commom interface for strings in several encodings. They also contains several hooks which can be used by luatex and xetex. The code is organized here with pseudo-guards, so we start with the basic commands.

Tools But first, a couple of tools. The first one makes global a local variable. This is not the best solution, but it works.

```
1033 \def\bbl@toglobal#1{\global\let#1#1}
1034 \def\bbl@recatcode#1{%
1035
      \@tempcnta="7F
      \def\bbl@tempa{%
1036
        \ifnum\@tempcnta>"FF\else
1037
          \catcode\@tempcnta=#1\relax
1038
1039
          \advance\@tempcnta\@ne
1040
          \expandafter\bbl@tempa
        \fi}%
1041
1042
      \bbl@tempa}
```

The second one. We need to patch \@uclclist, but it is done once and only if \SetCase is used or if strings are encoded. The code is far from satisfactory for several reasons, including the fact \@uclclist is not a list any more. Therefore a package option is added to ignore it. Instead of gobbling the macro getting the next two elements (usually \reserved@a), we pass it as argument to \bbl@uclc. The parser is restarted inside \ $\langle lang \rangle$ @bbl@uclc because we do not know how many expansions are necessary (depends on whether strings are encoded). The last part is tricky – when uppercasing, we have:

```
% \let\bbl@tolower\@empty\bbl@toupper\@empty
%
```

and starts over (and similarly when lowercasing).

```
1043 \@ifpackagewith{babel}{nocase}%
      {\let\bbl@patchuclc\relax}%
      {\def\bbl@patchuclc{%
1045
        \global\let\bbl@patchuclc\relax

Parse the encoding info to get the label, input, and font parts.

Select the behaviour of \SetString. Thre are two main cases, depending of if there is an optional argument: without it and strings=encoded, strings are defined always; otherwise, they are set only if they are still undefined (ie, fallback values). With labelled blocks and strings=encoded, define the strings, but with another value, define strings only if the current label or font encoding is the value of strings; otherwise (ie, no strings or a block whose label is not in strings=) do nothing.

We presume the current block is not loaded, and therefore set (above) a couple of default values to gobble the arguments. Then, these macros are redefined if necessary according to several parameters.

There are two versions of \bbl@scswitch. The first version is used when ldfs are read, and it makes sure $\langle group \rangle \langle language \rangle$ is reset, but only once (\bbl@screset is used to keep track of this). The second version is used in the preamble and packages loaded after babel and does nothing. The macro \bbl@forlang loops \bbl@L but its body is executed only if the value is in \BabelLanguages (inside babel) or \date $\langle language \rangle$ is defined (after babel has been loaded). There are also two version of \bbl@forlang. The first one skips the current iteration if the language is not in \BabelLanguages (used in ldfs), and the second one skips undefined languages (after babel has been loaded).

```

```

Now we define commands to be used inside \StartBabelCommands.

Strings The following macro is the actual definition of \SetString when it is "active"

First save the "switcher". Create it if undefined. Strings are defined only if undefined (ie, like \providescommand). With the event stringprocess you can preprocess the string by manipulating the value of \BabelString. If there are several hooks assigned to this event, preprocessing is done in the same order as defined. Finally, the string is set.

```
1184 \def\bbl@setstring#1#2{%
     \bbl@forlang\bbl@tempa{%
       \edef\bbl@LC{\bbl@tempa\expandafter\@gobble\string#1}%
1186
       \@ifundefined{\bbl@LC}% eg, \germanchaptername
1187
         {\global\expandafter
1188
          \bbl@add\csname\bbl@G\bbl@tempa\expandafter\endcsname\expandafter
1189
1190
             {\expandafter\bbl@scset\expandafter#1\csname\bbl@LC\endcsname}}%
         {}%
1191
       \def\BabelString{#2}%
       \bbl@usehooks{stringprocess}{}%
1193
       \expandafter\bbl@stringdef
1194
         \csname\bbl@LC\expandafter\endcsname\expandafter{\BabelString}}}
```

Now, some additional stuff to be used when encoded strings are used. Captions then include \bbl@encoded for string to be expanded in case transformations. It is \relax by default, but in \MakeUppercase and \MakeLowercase its value is a modified expandable \@changed@cmd.

```
1196 \ifx\bbl@opt@strings\relax
     \def\bbl@scset#1#2{\def#1{\bbl@encoded#2}}
1197
1198
     \bbl@patchuclc
1199
     \let\bbl@encoded\relax
     \def\bbl@encoded@uclc#1{%
1200
        \@inmathwarn#1%
1201
        \expandafter\ifx\csname\cf@encoding\string#1\endcsname\relax
1202
          \expandafter\ifx\csname ?\string#1\endcsname\relax
1203
            \TextSymbolUnavailable#1%
1204
          \else
1205
1206
            \csname ?\string#1\endcsname
          \fi
1207
1208
1209
          \csname\cf@encoding\string#1\endcsname
1210
        \fi}
1211 \else
1212 \def\bbl@scset#1#2{\def#1{#2}}
1213 \fi
```

Define \SetStringLoop, which is actually set inside \StartBabelCommands. The

current definition is somewhat complicated because we need a count, but \count@ is not under our control (remember \SetString may call hooks).

```
1214 \langle *Macros local to BabelCommands \rangle \rangle \equiv
1215 \def\SetStringLoop##1##2{%
         \def\bbl@templ###1{\expandafter\noexpand\csname##1\endcsname}%

1287 \begingroup
1288 \edef\@SF{\spacefactor\the\spacefactor}#1\@SF
1289 \endgroup}
```

7.11 Making glyphs available

This section makes a number of glyphs available that either do not exist in the OT1 encoding and have to be 'faked', or that are not accessible through Tlenc.def.

7.11.1 Quotation marks

\quotedblbase In the T1 encoding the opening double quote at the baseline is available as a separate character, accessible via \quotedblbase. In the OT1 encoding it is not available, therefore we make it available by lowering the normal open quote character to the baseline. 1290 \ProvideTextCommand{\quotedblbase}{0T1}{% \save@sf@q{\set@low@box{\textquotedblright\/}% \box\z@\kern-.04em\bbl@allowhyphens}} Make sure that when an encoding other than 0T1 or T1 is used this glyph can still be typeset. 1293 \ProvideTextCommandDefault{\quotedblbase}{% 1294 \UseTextSymbol{OT1}{\quotedblbase}} \quotesinglbase We also need the single quote character at the baseline. 1295 \ProvideTextCommand{\quotesinglbase}{0T1}{% \save@sf@q{\set@low@box{\textquoteright\/}% \box\z@\kern-.04em\bbl@allowhyphens}} 1297 Make sure that when an encoding other than OT1 or T1 is used this glyph can still be typeset. 1298 \ProvideTextCommandDefault{\quotesinglbase}{% \UseTextSymbol{OT1}{\quotesinglbase}} \quillemotleft The guillemet characters are not available in OT1 encoding. They are faked. \guillemotright 1300 \ProvideTextCommand{\guillemotleft}{OT1}{% \ifmmode 1301 1302 \11 \else 1303 1304 \save@sf@q{\nobreak 1305 \raise.2ex\hbox{\$\scriptscriptstyle\ll\$}\bbl@allowhyphens}% \fi} 1306 1307 \ProvideTextCommand{\guillemotright}{0T1}{% \ifmmode 1308 1309 \gg \else 1310 1311 \save@sf@q{\nobreak 1312 \raise.2ex\hbox{\$\scriptscriptstyle\gg\$}\bbl@allowhyphens}% Make sure that when an encoding other than OT1 or T1 is used these glyphs can still be typeset. 1314 \ProvideTextCommandDefault{\guillemotleft}{% 1315 \UseTextSymbol{OT1}{\guillemotleft}} 1316 \ProvideTextCommandDefault{\quillemotright}{% 1317 \UseTextSymbol{OT1}{\guillemotright}} \quilsinglleft The single quillemets are not available in OT1 encoding. They are faked. $\label{lem:command} $$ \sup_{1318 \in \mathbb{R}} \Pr (0T1)_{\%} $$$ 1319 \ifmmode 1320 <% \else 1321 \save@sf@q{\nobreak \raise.2ex\hbox{\$\scriptscriptstyle<\$}\bbl@allowhyphens}% 1323 \fi} 1324

1325 \ProvideTextCommand{\guilsinglright}{0T1}{%

Make sure that when an encoding other than 0T1 or T1 is used these glyphs can still be typeset.

```
1332 \ProvideTextCommandDefault{\guilsinglleft}{%
1333 \UseTextSymbol{0T1}{\guilsinglleft}}
1334 \ProvideTextCommandDefault{\guilsinglright}{%
1335 \UseTextSymbol{0T1}{\guilsinglright}}
```

7.11.2 Letters

\ij The dutch language uses the letter 'ij'. It is available in T1 encoded fonts, but not \IJ in the OT1 encoded fonts. Therefore we fake it for the OT1 encoding.

```
1336 \DeclareTextCommand{\ij}{0T1}{%
1337    i\kern-0.02em\bbl@allowhyphens    j}
1338 \DeclareTextCommand{\IJ}{0T1}{%
1339    I\kern-0.02em\bbl@allowhyphens    J}
1340 \DeclareTextCommand{\ij}{T1}{\char188}
1341 \DeclareTextCommand{\IJ}{T1}{\char156}
```

Make sure that when an encoding other than 0T1 or T1 is used these glyphs can still be typeset.

```
1342 \ProvideTextCommandDefault{\ij}{%
1343 \UseTextSymbol{0T1}{\ij}}
1344 \ProvideTextCommandDefault{\IJ}{%
1345 \UseTextSymbol{0T1}{\IJ}}
```

\dj The croatian language needs the letters \dj and \DJ; they are available in the T1 \DJ encoding, but not in the OT1 encoding by default.

Some code to construct these glyphs for the OT1 encoding was made available to me by Stipcevic Mario, (stipcevic@olimp.irb.hr).

```
1346 \def\crrtic@{\hrule height0.1ex width0.3em}

     1414 \ProvideTextCommandDefault{\frqq}{\UseTextSymbol{0T1}\frqq}
```

7.11.4 Umlauts and tremas

The command \" needs to have a different effect for different languages. For German for instance, the 'umlaut' should be positioned lower than the default position for placing it over the letters a, o, u, A, O and U. When placed over an e, i, E or I it can retain its normal position. For Dutch the same glyph is always placed in the lower position.

\umlauthigh To be able to provide both positions of \" we provide two commands to switch the \umlautlow positioning, the default will be \umlauthigh (the normal positioning).

```
1415 \def\umlauthigh{%
1416 \def\bbl@umlauta##1{\leavevmode\bgroup%
         \expandafter\accent\csname\f@encoding dqpos\endcsname
1417
         ##1\bbl@allowhyphens\egroup}%
1419 \let\bbl@umlaute\bbl@umlauta}
1420 \def\umlautlow{%
    \def\bbl@umlauta{\protect\lower@umlaut}}
1422 \def\umlautelow{%
1423 \def\bbl@umlaute{\protect\lower@umlaut}}
1424 \umlauthigh
```

\lower@umlaut The command \lower@umlaut is used to position the \" closer the the letter. We want the umlaut character lowered, nearer to the letter. To do this we need an extra $\langle dimen \rangle$ register.

```
1425 \expandafter\ifx\csname U@D\endcsname\relax
1426 \csname newdimen\endcsname\U@D
1427∖fi
```

The following code fools T_FX's make_accent procedure about the current x-height of the font to force another placement of the umlaut character. First we have to save the current x-height of the font, because we'll change this font dimension and this is always done globally.

Then we compute the new x-height in such a way that the umlaut character is lowered to the base character. The value of .45ex depends on the METAFONT parameters with which the fonts were built. (Just try out, which value will look best.) If the new x-height is too low, it is not changed. Finally we call the \accent primitive, reset the old x-height and insert the base character in the argument.

```
1428 \def\lower@umlaut#1{%
     \leavevmode\bgroup
        \U@D 1ex%
1430
        {\setbox\z@\hbox{%
1431
          \expandafter\char\csname\f@encoding dqpos\endcsname}%
1432
          \dimen@ -.45ex\advance\dimen@\ht\z@
1433
          \ifdim lex<\dimen@ \fontdimen5\font\dimen@ \fi}%
1434
        \expandafter\accent\csname\f@encoding dgpos\endcsname
1435
        \fontdimen5\font\U@D #1%
1436
1437
     \egroup}
```

For all vowels we declare \" to be a composite command which uses \bbl@umlauta or \bbl@umlaute to position the umlaut character. We need to be sure that these definitions override the ones that are provided when the package fontenc with option OT1 is used. Therefore these declarations are postponed until the beginning of the document. Note these definitions only apply to some languages, but babel sets them for all languages – you may want to redefine \bbl@umlauta and/or \bbl@umlaute for a language in the corresponding ldf (using the babel switching mechanism, of course).

```
1438 \AtBeginDocument {%
    \DeclareTextCompositeCommand{\"}{OT1}{a}{\bbl@umlauta{a}}%
    1440
1441
    \DeclareTextCompositeCommand{\"}{OT1}{i}{\bbl@umlaute{\i}}%
    \label{lem:local_composite} $$\DeclareTextCompositeCommand{\"}{0T1}{o}{\bbl@umlauta{o}}} $$
1443
    \DeclareTextCompositeCommand{\"}{OT1}{u}{\bbl@umlauta{u}}%
    \DeclareTextCompositeCommand{\"}{OT1}{A}{\bbl@umlauta{A}}%
    1446
    \label{lem:local_local_command} $$\DeclareTextCompositeCommand{\"}_{I}_{OT1}_{I}_{\bbl@umlaute_{I}}_{\end{tabular}}$$
1448
    1449
1450 }

1458
```

8 The kernel of Babel (only LATEX)

1459 \fi

8.1 The redefinition of the style commands

The rest of the code in this file can only be processed by \LaTeX X, so we check the current format. If it is plain \Tau EX, processing should stop here. But, because of the need to limit the scope of the definition of \format, a macro that is used locally in the following \if statement, this comparison is done inside a group. To prevent \Tau EX from complaining about an unclosed group, the processing of the command

\endinput is deferred until after the group is closed. This is accomplished by the command \aftergroup.

```
1460 {\def\format{lplain}
1461 \ifx\fmtname\format
1462 \else
1463 \def\format{LaTeX2e}
1464 \ifx\fmtname\format
1465 \else
1466 \aftergroup\endinput
1467 \fi
1468 \fi}
```

8.2 Cross referencing macros

The LATEX book states:

The *key* argument is any sequence of letters, digits, and punctuation symbols; upper- and lowercase letters are regarded as different.

When the above quote should still be true when a document is typeset in a language that has active characters, special care has to be taken of the category codes of these characters when they appear in an argument of the cross referencing macros.

When a cross referencing command processes its argument, all tokens in this argument should be character tokens with category 'letter' or 'other'.

The only way to accomplish this in most cases is to use the trick described in the T_EXbook [?] (Appendix D, page 382). The primitive \meaning applied to a token expands to the current meaning of this token. For example, '\meaning\A' with \A defined as '\def\A#1{\B}' expands to the characters 'macro:#1->\B' with all category codes set to 'other' or 'space'.

\newlabel The macro \label writes a line with a \newlabel command into the .aux file to define labels.

\@newl@bel We need to change the definition of the LATEX-internal macro \@newl@bel. This is needed because we need to make sure that shorthand characters expand to their non-active version.

The following package options control which macros are to be redefined.

First we open a new group to keep the changed setting of \protect local and then we set the @safe@actives switch to true to make sure that any shorthand that appears in any of the arguments immediately expands to its non-active self.

```
1476 \ifx\bbl@opt@safe\@empty\else
1477 \def\@newl@bel#1#2#3{%
1478 {\@safe@activestrue
1479 \@ifundefined{#1@#2}%
1480 \relax
1481 {\gdef\@multiplelabels{%
```

```
1482 \@latex@warning@no@line{There were multiply-defined labels}}%
1483 \@latex@warning@no@line{Label '#2' multiply defined}}%
1484 \global\@namedef{#1@#2}{#3}}}
```

\@testdef An internal IATEX macro used to test if the labels that have been written on the .aux file have changed. It is called by the \enddocument macro. This macro needs to be completely rewritten, using \meaning. The reason for this is that in some cases the expansion of \#1@#2 contains the same characters as the #3; but the character codes differ. Therefore IATEX keeps reporting that the labels may have changed.

```
1485 \CheckCommand*\@testdef[3]{%
1486 \def\reserved@a{#3}%
1487 \expandafter\ifx\csname#1@#2\endcsname\reserved@a
1488 \else
1489 \@tempswatrue
1490 \fi}
```

Now that we made sure that \@testdef still has the same definition we can rewrite it. First we make the shorthands 'safe'.

```
1491 \def\@testdef#1#2#3{%
1492 \@safe@activestrue
```

Then we use \bbl@tempa as an 'alias' for the macro that contains the label which is being checked.

Then we define \bbl@tempb just as \@newl@bel does it.

```
1494 \def\bbl@tempb{#3}%
1495 \@safe@activesfalse
```

When the label is defined we replace the definition of \bbl@tempa by its meaning.

```
1496 \ifx\bbl@tempa\relax
1497 \else
1498 \edef\bbl@tempa{\expandafter\strip@prefix\meaning\bbl@tempa}%
1499 \fi
```

We do the same for \bbl@tempb.

1500 \edef\bbl@tempb{\expandafter\strip@prefix\meaning\bbl@tempb}%

If the label didn't change, \bbl@tempa and \bbl@tempb should be identical macros.

```
1501 \ifx\bbl@tempa\bbl@tempb
1502 \else
1503 \@tempswatrue
1504 \fi}
1505\fi
```

\ref The same holds for the macro \ref that references a label and \pageref to reference a page. So we redefine \ref and \pageref. While we change these macros, we make them robust as well (if they weren't already) to prevent problems if they should become expanded at the wrong moment.

```
1506 \@expandtwoargs\in@{R}\bbl@opt@safe
1507 \ifin@
1508 \bbl@redefinerobust\ref#1{%
1509 \@safe@activestrue\org@ref{#1}\@safe@activesfalse}
1510 \bbl@redefinerobust\pageref#1{%
1511 \@safe@activestrue\org@pageref{#1}\@safe@activesfalse}
1512 \else
```

```
1513 \let\org@ref\ref
1514 \let\org@pageref\pageref
1515\fi
```

\@citex The macro used to cite from a bibliography, \cite, uses an internal macro, \@citex. It is this internal macro that picks up the argument(s), so we redefine this internal macro and leave \cite alone. The first argument is used for typesetting, so the shorthands need only be deactivated in the second argument.

```
1516 \@expandtwoargs\in@{B}\bbl@opt@safe
1517 \ifin@
1518 \bbl@redefine\@citex[#1]#2{%
1519 \@safe@activestrue\edef\@tempa{#2}\@safe@activesfalse
1520 \org@@citex[#1]{\@tempa}}
```

Unfortunately, the packages natbib and cite need a different definition of \@citex... To begin with, natbib has a definition for \@citex with three arguments... We only know that a package is loaded when \begin{document} is executed, so we need to postpone the different redefinition.

```
1521 \AtBeginDocument{%
1522 \@ifpackageloaded{natbib}{%
```

Notice that we use \def here instead of \bbl@redefine because \org@citex is already defined and we don't want to overwrite that definition (it would result in parameter stack overflow because of a circular definition).

(Recent versions of natbib change dynamically \@citex, so PR4087 doesn't seem fixable in a simple way. Just load natbib before.)

The package cite has a definition of \@citex where the shorthands need to be turned off in both arguments.

```
1527 \AtBeginDocument{%
1528 \@ifpackageloaded{cite}{%
1529 \def\@citex[#1]#2{%
1530 \@safe@activestrue\org@@citex[#1]{#2}\@safe@activesfalse}%
1531 \}{}}
```

 $\mbox{\colored}$ The macro $\mbox{\colored}$ which is used to instruct BiBTEX to extract uncited references from the database.

```
1532 \bbl@redefine\nocite#1{%
1533 \@safe@activestrue\org@nocite{#1}\@safe@activesfalse}
```

The macro that is used in the .aux file to define citation labels. When packages such as natbib or cite are not loaded its second argument is used to typeset the citation label. In that case, this second argument can contain active characters but is used in an environment where \@safe@activestrue is in effect. This switch needs to be reset inside the \hbox which contains the citation label. In order to determine during .aux file processing which definition of \bibcite is needed we define \bibcite in such a way that it redefines itself with the proper definition.

```
1534 \bbl@redefine\bibcite{%
```

We call \bbl@cite@choice to select the proper definition for \bibcite. This new definition is then activated.

```
1535 \bbl@cite@choice
1536 \bibcite}
```

\bbl@bibcite The macro \bbl@bibcite holds the definition of \bibcite needed when neither natbib nor cite is loaded.

```
\def\bbl@bibcite#1#2{%
1537
```

1538 \org@bibcite{#1}{\@safe@activesfalse#2}}

\bbl@cite@choice The macro \bbl@cite@choice determines which definition of \bibcite is needed.

```
\def\bbl@cite@choice{%
```

First we give \bibcite its default definition.

```
\global\let\bibcite\bbl@bibcite
```

Then, when natbib is loaded we restore the original definition of \bibcite.

\@ifpackageloaded{natbib}{\global\let\bibcite\org@bibcite}{}% 1541

For cite we do the same.

\@ifpackageloaded{cite}{\global\let\bibcite\org@bibcite}{}%

Make sure this only happens once.

```
1543
       \global\let\bbl@cite@choice\relax}
```

When a document is run for the first time, no .aux file is available, and \bibcite will not yet be properly defined. In this case, this has to happen before the document starts.

```
\AtBeginDocument{\bbl@cite@choice}
```

\@bibitem One of the two internal LATEX macros called by \bibitem that write the citation label on the .aux file.

```
\bbl@redefine\@bibitem#1{%
1545
```

1546 \@safe@activestrue\org@@bibitem{#1}\@safe@activesfalse}

1547 \else

\let\org@nocite\nocite 1548

\let\org@@citex\@citex

\let\org@bibcite\bibcite

\let\org@@bibitem\@bibitem 1551

1552 \fi

8.3 Marks

\markright Because the output routine is asynchronous, we must pass the current language attribute to the head lines, together with the text that is put into them. To achieve this we need to adapt the definition of \markright and \markboth somewhat.

```
1553 \bbl@redefine\markright#1{%
```

First of all we temporarily store the language switching command, using an expanded definition in order to get the current value of \languagename.

```
\edef\bbl@tempb{\noexpand\protect
```

1555 \noexpand\foreignlanguage{\languagename}}%

Then, we check whether the argument is empty; if it is, we just make sure the scratch token register is empty.

```
\def\bbl@arg{#1}%
1556
```

\toks@{}% 1558

\else 1559

¹⁵⁵⁷ \ifx\bbl@arg\@empty

Next, we store the argument to \markright in the scratch token register, together with the expansion of \bbl@tempb (containing the language switching command) as defined before. This way these commands will not be expanded by using \edef later on, and we make sure that the text is typeset using the correct language settings. While doing so, we make sure that active characters that may end up in the mark are not disabled by the output routine kicking in while \@safe@activestrue is in effect.

```
1560 \expandafter\toks@\expandafter{%
1561 \bbl@tempb{\protect\bbl@restore@actives#1}}%
1562 \fi
```

Then we define a temporary control sequence using \edef.

```
1563 \edef\bbl@tempa{%
```

1593 \bbl@tempc

When \bbl@tempa is executed, only \languagename will be expanded, because of the way the token register was filled.

```
1564 \noexpand\org@markright{\the\toks@}}%
1565 \bbl@tempa
1566}
```

\markboth \@mkboth The definition of \markboth is equivalent to that of \markright, except that we need two token registers. The documentclasses report and book define and set the headings for the page. While doing so they also store a copy of \markboth in \@mkboth. Therefore we need to check whether \@mkboth has already been set. If so we need to do that again with the new definition of \makrboth.

```
1567 \ifx\@mkboth\markboth
1568 \def\bbl@tempc{\let\@mkboth\markboth}
1569 \else
1570 \def\bbl@tempc{}
1571 \fi
```

Now we can start the new definition of \markboth

```
1572 \bbl@redefine\markboth#1#2{%
     \edef\bbl@tempb{\noexpand\protect
        \noexpand\foreignlanguage{\languagename}}%
1574
1575
      \def\bbl@arg{#1}%
     \ifx\bbl@arg\@empty
1576
1577
        \toks@{}%
1578
     \else
      \expandafter\toks@\expandafter{%
1579
                 \bbl@tempb{\protect\bbl@restore@actives#1}}%
1580
     \fi
1581
1582
     \def\bbl@arg{#2}%
     \ifx\bbl@arg\@empty
        \toks8{}%
1584
1585
     \else
       \expandafter\toks8\expandafter{%
1586
                 \bbl@tempb{\protect\bbl@restore@actives#2}}%
1587
1588
     \fi
     \edef\bbl@tempa{%

       \noexpand \org@markboth{\the\toks@}{\the\toks8}}\%
1590
1591
     \bbl@tempa
1592 }
 and copy it to \@mkboth if necesary.
```

8.4 Preventing clashes with other packages

8.4.1 ifthen

\ifthenelse

Sometimes a document writer wants to create a special effect depending on the page a certain fragment of text appears on. This can be achieved by the following piece of code:

```
% \ifthenelse{\isodd{\pageref{some:label}}}
% {code for odd pages}
% {code for even pages}
%
```

In order for this to work the argument of \isodd needs to be fully expandable. With the above redefinition of \pageref it is not in the case of this example. To overcome that, we add some code to the definition of \ifthenelse to make things work.

The first thing we need to do is check if the package ifthen is loaded. This should be done at \begin{document} time.

```
1594 \@expandtwoargs\in@{R}\bbl@opt@safe
1595 \ifin@
1596 \AtBeginDocument{%
1597 \@ifpackageloaded{ifthen}{%
Then we can redefine \ifthenelse:
1598 \bbl@redefine@long\ifthenelse#1#2#3{%
```

We want to revert the definition of \pageref and \ref to their original definition for the duration of \ifthenelse, so we first need to store their current meanings.

```
1599 % \ifx\pageref\bbl@temp@pref\else
1600 \let\bbl@temp@pref\pageref
1601 \let\pageref\org@pageref
1602 % \fi
1603 % \ifx\ref\bbl@temp@ref\else
1604 \let\bbl@temp@ref\ref
1605 \let\ref\org@ref
1606 % \fi
```

Then we can set the \@safe@actives switch and call the original \ifthenelse. In order to be able to use shorthands in the second and third arguments of \ifthenelse the resetting of the switch and the definition of \pageref happens inside those arguments. When the package wasn't loaded we do nothing.

```
1607
             \@safe@activestrue
1608 \show\ref
1609
            \org@ifthenelse{#1}{%
1610
               \let\pageref\bbl@temp@pref
               \let\ref\bbl@temp@ref
1611
               \@safe@activesfalse
1612
               #2}{%
1613
               \let\pageref\bbl@temp@pref
1614
               \let\ref\bbl@temp@ref
1615
               \@safe@activesfalse
1616
1617
               #3}%
1618
            }%
1619
          }{}%
1620
```

8.4.2 varioref

\vrefpagenum

When the package varioref is in use we need to modify its internal command \@@vpageref in order to prevent problems when an active character ends up in the \Ref argument of \vref.

```
\AtBeginDocument{%
1621
1622
        \@ifpackageloaded{varioref}{%
          \bbl@redefine\@@vpageref#1[#2]#3{%
1623
1624
            \@safe@activestrue
1625
            \org@@vpageref{#1}[#2]{#3}%
            \@safe@activesfalse}%
1626
```

The same needs to happen for \vrefpagenum.

```
\bbl@redefine\vrefpagenum#1#2{%
1627
1628
            \@safe@activestrue
1629
            \org@vrefpagenum{#1}{#2}%
1630
            \@safe@activesfalse}%
```

The package varioref defines \Ref to be a robust command wich uppercases the first character of the reference text. In order to be able to do that it needs to access the exandable form of \ref. So we employ a little trick here. We redefine the (internal) command \Ref. to call \org@ref instead of \ref. The disadvantgage of this solution is that whenever the derfinition of \Ref changes, this definition needs to be updated as well.

```
\expandafter\def\csname Ref \endcsname#1{%
1631
            \protected@edef\@tempa{\org@ref{#1}}\expandafter\MakeUppercase\@tempa}
1632
1633
1634
1635 \fi
```

8.4.3 hhline

\hhline Delaying the activation of the shorthand characters has introduced a problem with the hhline package. The reason is that it uses the ':' character which is made active by the french support in babel. Therefore we need to reload the package when the ':' is an active character.

So at \begin{document} we check whether hhline is loaded.

```
1636 \AtEndOfPackage{%
     \AtBeginDocument{%
1637
        \@ifpackageloaded{hhline}%
```

Then we check whether the expansion of \normal@char: is not equal to \relax.

```
{\expandafter\ifx\csname normal@char\string:\endcsname\relax
1639
1640
```

In that case we simply reload the package. Note that this happens after the category code of the @-sign has been changed to other, so we need to temporarily change it to letter again.

```
1641
             \makeatletter
             \def\@currname{hhline}\input{hhline.sty}\makeatother
1642
           \fi}%
1643
1644
          {}}}
```

8.4.4 hyperref

\pdfstringdefDisableCommands

A number of interworking problems between babel and hyperref are tackled by hyperref itself. The following code was introduced to prevent some annoying

warnings but it broke bookmarks. This was quickly fixed in hyperref, which essentially made it no-op. However, it will not removed for the moment because hyperref is expecting it.

```
1645 \AtBeginDocument{%
1646 \@ifundefined{pdfstringdefDisableCommands}%
1647 {}%
1648 {\pdfstringdefDisableCommands{%
1649 \languageshorthands{system}}%
1650 }%
```

8.4.5 fancyhdr

\FOREIGNLANGUAGE

The package fancyhor treats the running head and fout lines somewhat differently as the standard classes. A symptom of this is that the command \foreignlanguage which babel adds to the marks can end up inside the argument of \MakeUppercase. To prevent unexpected results we need to define \FOREIGNLANGUAGE here.

```
1652 \DeclareRobustCommand{\FOREIGNLANGUAGE}[1]{%
1653 \lowercase{\foreignlanguage{#1}}}
```

\substitutefontfamily

The command \substitutefontfamily creates an .fd file on the fly. The first argument is an encoding mnemonic, the second and third arguments are font family names.

```
1654 \def\substitutefontfamily#1#2#3{%
                  \lowercase{\immediate\openout15=#1#2.fd\relax}%
1655
                  \immediate\write15{%
1656
                         \string\ProvidesFile{#1#2.fd}%
1657
                          [\the\year/\two@digits{\the\month}/\two@digits{\the\day}
1658
                            \space generated font description file]^^J
1659
                         \string\DeclareFontFamily{#1}{#2}{}^^J
1660
1661
                         \left(m\right)^{-2} m^{-2} m^{
                         \string\DeclareFontShape{#1}{#2}{m}{it}{<->ssub * #3/m/it}{}^^J
1662
                         \string\DeclareFontShape{#1}{#2}{m}{sl}{<->ssub * #3/m/sl}{}^^J
1663
                         \string\DeclareFontShape{#1}{#2}{m}{sc}{<->ssub * #3/m/sc}{}^^J
1664
                         \string\DeclareFontShape{#1}{#2}{b}{n}{<->ssub * #3/bx/n}{}^^J
1665
                         \string\DeclareFontShape{#1}{#2}{b}{it}{<->ssub * #3/bx/it}{}^^J
1666
                         \string\DeclareFontShape{#1}{#2}{b}{sl}{<->ssub * #3/bx/sl}{}^^J
1667
                         \string\DeclareFontShape{#1}{#2}{b}{sc}{<->ssub * #3/bx/sc}{}^^J
1668
                         }%
1669
                  \closeout15
1670
1671
```

This command should only be used in the preamble of a document.

1672 @onlypreamble substitute font family

8.5 Encoding issues

Because documents may use non-ASCII font encodings, we make sure that the logos of T_EX and I^AT_EX always come out in the right encoding. There is a list of non-ASCII encodings. Unfortunately, fontenc deletes its package options, so we must guess which encodings has been loaded by traversing \@filelist to search for $\langle enc \rangle$ enc.def. If a non-ASCII has been loaded, we define versions of \TeX and \LaTeX for them using \ensureascii. The default ASCII encoding is set, too (in reverse order): the "main" encoding (when the document begins), the last loaded, or OT1.

\ensureascii

```
1673 \newcommand\BabelNonASCII{LGR,X2,OT2,OT3,OT6,LHE,LWN,LMA,LMC,LMS,LMU,}
1674 \let\org@TeX\TeX
1675 \let\org@LaTeX\LaTeX
1676 \let\ensureascii\@firstofone
1677 \AtBeginDocument{%
1678
     \in@false
     \bbl@loopx\bbl@tempa\BabelNonASCII{% is there a non-ascii enc?
1679
       \ifin@\else
1680
         \edef\bbl@tempb{{,\bbl@tempa enc.def,}{,\@filelist,}}%
1681
         \lowercase\expandafter{\expandafter\in@\bbl@tempb}%
1682
1683
1684
     \ifin@ % if a non-ascii has been loaded
1685
       \def\ensureascii#1{{\fontencoding{0T1}\selectfont#1}}%
       \DeclareTextCommandDefault{\TeX}{\org@TeX}%
1686
       \DeclareTextCommandDefault{\LaTeX}{\org@LaTeX}%
1687
       1688
       \def\bl@tempc#1ENC.DEF#2\@({\%})
1689
         \ifx\ensuremath{\mbox{Qempty#2}\else}
1690
           \@ifundefined{T@#1}%
1691
             {}%
1692
             {\@expandtwoargs\in@{,#1,}{,\BabelNonASCII,}%
1693
              \ifin@
1694
                \DeclareTextCommand{\TeX}{#1}{\ensureascii{\org@TeX}}%
                \DeclareTextCommand{\LaTeX}{#1}{\ensureascii{\org@LaTeX}}%
1696
              \else
1697
1698
                \def\ensureascii##1{{\fontencoding{#1}\selectfont##1}}%
1699
              \fi}%
1700
         \fi}%
1701
       \bbl@loopx\bbl@tempa\@filelist{\expandafter\bbl@tempb\bbl@tempa\@@}%
       1702
1703
       \ifin@\else
         \edef\ensureascii#1{{%
1704
           \noexpand\fontencoding{\cf@encoding}\noexpand\selectfont#1}}%
1705
1706
       \fi
1707
     \fi}
```

Now comes the old deprecated stuff (with a little change in 3.91, for fontspec). The first thing we need to do is to determine, at \begin{document}, which latin fontencoding to use.

\latinencoding

When text is being typeset in an encoding other than 'latin' (0T1 or T1), it would be nice to still have Roman numerals come out in the Latin encoding. So we first assume that the current encoding at the end of processing the package is the Latin encoding.

 ${\tt 1708 \ AtEndOfPackage \{\ edef\ latinencoding \{\ cf@encoding \}\}}$

But this might be overruled with a later loading of the package fontenc. Therefore we check at the execution of \begin{document} whether it was loaded with the T1 option. The normal way to do this (using \@ifpackageloaded) is disabled for this package. Now we have to revert to parsing the internal macro \@filelist which contains all the filenames loaded.

```
1709 \AtBeginDocument{%
1710 \@ifpackageloaded{fontspec}%
1711 {\xdef\latinencoding{EU\ifcase\bbl@engine\or2\or1\fi}}%
1712 {\gdef\latinencoding{0T1}%
```

```
1713 \ifx\cf@encoding\bbl@t@one
1714 \xdef\latinencoding{\bbl@t@one}%
1715 \else
1716 \@ifl@aded{def}{tlenc}{\xdef\latinencoding{\bbl@t@one}}{}%
1717 \fi}}
```

\latintext Then we can define the command \latintext which is a declarative switch to a latin font-encoding. Usage of this macro is deprecated.

```
1718 \DeclareRobustCommand{\latintext}{%
1719 \fontencoding{\latinencoding}\selectfont
1720 \def\encodingdefault{\latinencoding}}
```

\textlatin This command takes an argument which is then typeset using the requested font encoding. In order to avoid many encoding switches it operates in a local scope.

```
1721 \ifx\@undefined\DeclareTextFontCommand
1722 \DeclareRobustCommand{\textlatin}[1]{\leavevmode{\latintext #1}}
1723 \else
1724 \DeclareTextFontCommand{\textlatin}{\latintext}
1725 \fi
```

8.6 Local Language Configuration

\loadlocalcfg At some sites it may be necessary to add site-specific actions to a language definition file. This can be done by creating a file with the same name as the language definition file, but with the extension .cfg. For instance the file norsk.cfg will be loaded when the language definition file norsk.ldf is loaded. For plain-based formats we don't want to override the definition of \loadlocalcfg from plain.def.

```
1726 \ifx\loadlocalcfg\@undefined
    \@ifpackagewith{babel}{noconfigs}%
1728

1741
          \let\protect\@unexpandable@protect
1742
          \edef\reserved@a{\write#1{#3}}%
1743
          \reserved@a
1744
1745
        \endgroup
        \if@nobreak\ifvmode\nobreak\fi\fi}
1746
1747\fi
1748 (/core)
```

9 Internationalizing IAT_FX 2.09

Now that we're sure that the code is seen by LATEX only, we have to find out what the main (primary) document style is because we want to redefine some macros. This is only necessary for releases of LATEX dated before December 1991. Therefore this part of the code can optionally be included in babel.def by specifying the docstrip option names.

The standard styles can be distinguished by checking whether some macros are defined. In table ?? an overview is given of the macros that can be used for this purpose.

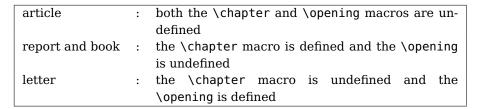

Table 1: How to determine the main document style

The macros that have to be redefined for the report and book document styles happen to be the same, so there is no need to distinguish between those two styles.

\doc@style

First a parameter \doc@style is defined to identify the current document style. This parameter might have been defined by a document style that already uses macros instead of hard-wired texts, such as artikell.sty [?], so the existence of \doc@style is checked. If this macro is undefined, i.e., if the document style is unknown and could therefore contain hard-wired texts, \doc@style is defined to the default value '0'.

```
1749 (*names)
1750 \ifx\@undefined\doc@style
1751 \def\doc@style{0}%
```

This parameter is defined in the following if construction (see table ??):

```
\ifx\@undefined\opening
1753
        \ifx\@undefined\chapter
          \def\doc@style{1}%
1754
        \else
1755
          \def\doc@style{2}%
1756
        \fi
1757
1758
     \else
        \def\doc@style{3}%
1760
     \fi%
1761 \fi%
```

Now here comes the real work: we start to redefine things and replace hard-wired texts by macros. These redefinitions should be carried out conditionally, in case it has already been done.

For the figure and table environments we have in all styles:

```
\label{the property of the p
```

The rest of the macros have to be treated differently for each style. When \doc@style still has its default value nothing needs to be done.

```
This means that babel.def is read after the article style, where no \chapter and
 \opening commands are defined^{28}.
 First we have the \tableofcontents, \listoffigures and \listoftables:
1766 \@ifundefined{contentsname}%
1767
        {\def\tableofcontents{\section*{\contentsname\@mkboth
1768
              {\uppercase{\contentsname}}}\uppercase{\contentsname}}}%
          \@starttoc{toc}}}{}
1769
1770 \@ifundefined{listfigurename}%
        {\def\listoffigures{\section*{\listfigurename\@mkboth
1771
              {\uppercase{\listfigurename}}{\uppercase{\listfigurename}}}%
         \@starttoc{lof}}}{}
1773
1774 \@ifundefined{listtablename}%
1775
        {\def\listoftables{\section*{\listtablename\@mkboth
1776
              {\uppercase{\listtablename}}}\
1777
          \@starttoc{lot}}}{}
 Then the \thebibliography and \theindex environments.
1778 \@ifundefined{refname}%
       {\def\thebibliography#1{\section*{\refname
1779
          \@mkboth{\uppercase{\refname}}}{\uppercase{\refname}}}%
1780
          \list{[\arabic{enumi}]}{\settowidth\labelwidth{[#1]}%
1781
            \leftmargin\labelwidth
1782
            \advance\leftmargin\labelsep
1783
1784
            \usecounter{enumi}}%
            \def\newblock{\hskip.11em plus.33em minus.07em}%
1785
1786
            \sloppy\clubpenalty4000\widowpenalty\clubpenalty
            \sfcode'\.=1000\relax}}{}
1787
1788 \@ifundefined{indexname}%
        {\def\theindex{\@restonecoltrue\if@twocolumn\@restonecolfalse\fi
1789
         \columnseprule \z@
1790
         \columnsep 35pt\twocolumn[\section*{\indexname}]%
1791
           \@mkboth{\uppercase{\indexname}}{\uppercase{\indexname}}%
1792
           \thispagestyle{plain}%
1793
           \parskip\z@ plus.3pt\parindent\z@\let\item\@idxitem}}{}
1794
 The abstract environment:
1795 \@ifundefined{abstractname}%
       {\def\abstract{\if@twocolumn
       \section*{\abstractname}%
1797
1798
       \else \small
1799
       \begin{center}%
       {\bf \tilde{z_0}}%
1800
       \end{center}%
1801
1802
       \quotation
1803
       \fi}}{}
 And last but not least, the macro \part:
1804 \@ifundefined{partname}%
1805 {\def\@part[#1]#2{\ifnum \c@secnumdepth >\m@ne
            \refstepcounter{part}%
            \addcontentsline{toc}{part}{\thepart
1807
  ^{28}A fact that was pointed out to me by Nico Poppelier and was already used in Piet van Oostrum's
 document style option nl.
```

1764 \ifcase \doc@style\relax

1765 \or

```
\hspace{1em}#1}\else
1808
          \addcontentsline{toc}{part}{#1}\fi
1809
       {\parindent\z@ \raggedright
1810
1811
        \ifnum \c@secnumdepth >\m@ne
          \Large \bf \partname{} \thepart
1812
          \par \nobreak
1813
1814
        \fi
        \huge \bf
1815
        #2\markboth{}{}\par}%
1816
1817
        \nobreak
1818
        \vskip 3ex\@afterheading}%
1819 } { }
```

This is all that needs to be done for the article style.

1820 \or

The next case is formed by the two styles book and report. Basically we have to do the same as for the article style, except now we must also change the \chapter command.

The tables of contents, figures and tables:

```
1821 \@ifundefined{contentsname}%
1822
        {\def\tableofcontents{\@restonecolfalse
1823
          \if@twocolumn\@restonecoltrue\onecolumn
1824
          \fi\chapter*{\contentsname\@mkboth
1825
              {\uppercase{\contentsname}}}{\uppercase{\contentsname}}}%
1826
          \@starttoc{toc}%
          \csname if@restonecol\endcsname\twocolumn
1827
          \csname fi\endcsname}}{}
1828
1829 \@ifundefined{listfigurename}%
        {\def\listoffigures{\@restonecolfalse
1830
          \if@twocolumn\@restonecoltrue\onecolumn
1831
1832
          \fi\chapter*{\listfigurename\@mkboth
              {\uppercase{\listfigurename}}{\uppercase{\listfigurename}}}%
1833
          \@starttoc{lof}%
1834
          \csname if@restonecol\endcsname\twocolumn
1835
          \csname fi\endcsname}}{}
1836
1837 \@ifundefined{listtablename}%
1838
        {\def\listoftables{\@restonecolfalse
          \if@twocolumn\@restonecoltrue\onecolumn
1839
1840
          \fi\chapter*{\listtablename\@mkboth
              {\uppercase{\listtablename}}{\uppercase{\listtablename}}}%
1841
          \@starttoc{lot}%
1842
1843
          \csname if@restonecol\endcsname\twocolumn
          \csname fi\endcsname}}{}
```

Again, the bibliography and index environments; notice that in this case we use \bibname instead of \refname as in the definitions for the article style. The reason for this is that in the article document style the term 'References' is used in the definition of \thebibliography. In the report and book document styles the term 'Bibliography' is used.

```
\def\newblock{\hskip.11em plus.33em minus.07em}%
1851
         \sloppy\clubpenalty4000\widowpenalty\clubpenalty
1852
         \sfcode'\.=1000\relax}}{}
1853
1854 \@ifundefined{indexname}%
        {\def\theindex{\@restonecoltrue\if@twocolumn\@restonecolfalse\fi
1855
        \columnseprule \z@
1856
1857
        \columnsep 35pt\twocolumn[\@makeschapterhead{\indexname}]%
1858
          \@mkboth{\uppercase{\indexname}}{\uppercase{\indexname}}%
       \thispagestyle{plain}%
1859
1860
        \parskip\z@ plus.3pt\parindent\z@ \let\item\@idxitem}}{}
 Here is the abstract environment:
1861 \@ifundefined{abstractname}%
        {\def\abstract{\titlepage
1862
        \null\vfil
        \begin{center}%
1864
        {\bf \abstractname}%
1865
        \end{center}}}{}
 And last but not least the \chapter, \appendix and \part macros.
1867 \@ifundefined{chaptername}{\def\@chapapp{\chaptername}}{}
1869 \@ifundefined{appendixname}%
        {\def\appendix{\par
1870
          \setcounter{chapter}{0}%
1871
1872
          \setcounter{section}{0}%
1873
          \def\@chapapp{\appendixname}%
1874
          \def\thechapter{\Alph{chapter}}}}{}
1875%
1876 \@ifundefined{partname}%
        {\left(\frac{\#1}{\#2}\right)} - 2\left(\frac{\pi}{\#2}\right)
1877
                \refstepcounter{part}%
1878
1879
                \addcontentsline{toc}{part}{\thepart
1880
                \hspace{1em}#1}\else
                \addcontentsline{toc}{part}{#1}\fi
1881
           \markboth{}{}%

1886
            \par
            \vskip 20pt \fi
1887
            \Huge \bf
1888
            #1\par}\@endpart}}{}%
1889
1890\or
```

Now we address the case where babel.def is read after the letter style. The letter document style defines the macro \opening and some other macros that are specific to letter. This means that we have to redefine other macros, compared to the previous two cases.

First two macros for the material at the end of a letter, the \cc and \encl macros.

```
\parbox[t]{\textwidth}%

{\@hangfrom{\rm \enclname : }\ignorespaces #1\strut}\par}}{}
```

The last thing we have to do here is to redefine the headings pagestyle:

This was the last of the four standard document styles, so if \doc@style has another value we do nothing and just close the if construction.

```
1904 \fi
1905 (/names)
```

Here ends the code that can be optionally included when a version of \LaTeX is in use that is dated *before* December 1991.

We also need to redefine a number of commands to ensure that the right font encoding is used, but this can't be done before babel.def is loaded.

10 Multiple languages

Plain T_EX version 3.0 provides the primitive \language that is used to store the current language. When used with a pre-3.0 version this function has to be implemented by allocating a counter.

```
1906 \langle *kernel \rangle
1907 \langle \langle Make\ sure\ ProvidesFile\ is\ defined \rangle \rangle
1908 \ ProvidesFile \{ switch.def \} [\langle \langle date \rangle \rangle\ \langle \langle version \rangle \rangle \} Babel switching mechanism]
1909 \langle \langle Load\ macros\ for\ plain\ if\ not\ LaTeX \rangle \rangle
1910 \langle \langle Define\ core\ switching\ macros \rangle \rangle
```

\adddialect The macro \adddialect can be used to add the name of a dialect or variant language, for which an already defined hyphenation table can be used.

```

```

\bbl@iflanguage executes code only of the language exists. Otherwise raises and error.

The argument of \bbl@fixname has to be a macro name, as it may get "fixed" if casing (lc/uc) is wrong. It's intented to fix a long-standing bug when \foreignlanguage and the like appear in a \MakeXXXcase. However, a lowercase form is not imposed to improve backward compatibility (perhaps you defined a language named MYLANG, but unfortunately mixed case names cannot be trapped).

1917 \def\bbl@fixname#1{%

\iflanguage Users might want to test (in a private package for instance) which language is currently active. For this we provide a test macro, \iflanguage, that has three arguments. It checks whether the first argument is a known language. If so, it compares the first argument with the value of \language. Then, depending on the result of the comparison, it executes either the second or the third argument.

```
1934 \def\iflanguage#1{%
      \bbl@iflanguage{#1}{%
1935
        \ifnum\csname \left(\text{lendcsname} = \language
1936
           \expandafter\@firstoftwo
1937
        \else
1938
           \expandafter\@secondoftwo
1940
        \{fi\}\}
```

10.1 Selecting the language

\selectlanguage

The macro \selectlanguage checks whether the language is already defined before it performs its actual task, which is to update \language and activate language-specific definitions.

To allow the call of \selectlanguage either with a control sequence name or with a simple string as argument, we have to use a trick to delete the optional escape character.

To convert a control sequence to a string, we use the \string primitive. Next we have to look at the first character of this string and compare it with the escape character. Because this escape character can be changed by setting the internal integer \escapechar to a character number, we have to compare this number with the character of the string. To do this we have to use TFX's backquote notation to specify the character as a number.

If the first character of the \string'ed argument is the current escape character, the comparison has stripped this character and the rest in the 'then' part consists of the rest of the control sequence name. Otherwise we know that either the argument is not a control sequence or \escapechar is set to a value outside of the character range 0-255.

If the user gives an empty argument, we provide a default argument for \string. This argument should expand to nothing.

```
1941 \let\bbl@select@type\z@
1942 \edef\selectlanguage{%
1943
     \noexpand\protect
     \expandafter\noexpand\csname selectlanguage \endcsname}
```

Because the command \selectlanguage could be used in a moving argument it expands to \protect\selectlanguage.. Therefore, we have to make sure that a macro \protect exists. If it doesn't it is \let to \relax.

1945 \ifx\@undefined\protect\let\protect\relax\fi

As LATEX 2.09 writes to files expanded whereas LATEX 2ε takes care not to expand the arguments of \write statements we need to be a bit clever about the way we add information to .aux files. Therefore we introduce the macro \xstring which should expand to the right amount of \string's.

```
1946\ifx\documentclass\@undefined
1947 \def\xstring{\string\string}
1948\else
1949 \let\xstring\string
1950\fi
```

Since version 3.5 babel writes entries to the auxiliary files in order to typeset table of contents etc. in the correct language environment.

\bbl@pop@language

But when the language change happens inside a group the end of the group doesn't write anything to the auxiliary files. Therefore we need T_EX 's aftergroup mechanism to help us. The command \aftergroup stores the token immediately following it to be executed when the current group is closed. So we define a temporary control sequence \bbl@pop@language to be executed at the end of the group. It calls \bbl@set@language with the name of the current language as its argument.

\bbl@language@stack

The previous solution works for one level of nesting groups, but as soon as more levels are used it is no longer adequate. For that case we need to keep track of the nested languages using a stack mechanism. This stack is called \bbl@language@stack and initially empty.

```
1951 \def\bbl@language@stack{}
```

When using a stack we need a mechanism to push an element on the stack and to retrieve the information afterwards.

\bbl@push@language \bbl@pop@language

The stack is simply a list of languagenames, separated with a '+' sign; the push function can be simple:

```
1952 \def\bbl@push@language{%
1953 \xdef\bbl@language@stack{\languagename+\bbl@language@stack}}
```

Retrieving information from the stack is a little bit less simple, as we need to remove the element from the stack while storing it in the macro \languagename. For this we first define a helper function.

\bbl@pop@lang

This macro stores its first element (which is delimited by the '+'-sign) in $\label{lem:lement}$ languagename and stores the rest of the string (delimited by '-') in its third argument.

```
1954 \def\bbl@pop@lang#1+#2-#3{%
1955 \edef\languagename{#1}\xdef#3{#2}}
```

The reason for the somewhat weird arrangement of arguments to the helper function is the fact it is called in the following way. This means that before \bbl@pop@lang is executed TEX first expands the stack, stored in \bbl@language@stack. The result of that is that the argument string of \bbl@pop@lang contains one or more language names, each followed by a '+'-sign (zero language names won't occur as this macro will only be called after something has been pushed on the stack) followed by the '-'-sign and finally the reference to the stack.

```
1956 \def\bbl@pop@language{%
1957 \expandafter\bbl@pop@lang\bbl@language@stack-\bbl@language@stack
1958 \expandafter\bbl@set@language\expandafter{\languagename}}
```

Once the name of the previous language is retrieved from the stack, it is fed to \bbl@set@language to do the actual work of switching everything that needs switching.

```
1959 \expandafter\def\csname selectlanguage \endcsname#1{%
      \verb|\ifnum| bbl@hymapsel=\\ @cclv\\let\\bbl@hymapsel\\tw@\\fi
1960
1961
      \bbl@push@language
1962
      \aftergroup\bbl@pop@language
      \bbl@set@language{#1}}
1963
```

\bbl@set@language

afterwards.

2000

The macro \bbl@set@language takes care of switching the language environment and of writing entries on the auxiliary files. For historial reasons, language names can be either language of \language. To catch either form a trick is used, but unfortunately as a side effect the catcodes of letters in \languagename are not well defined. The list of auxiliary files can be extended by redefining \BabelContentsFiles, but make sure they are loaded inside a group (as aux, toc, lof, and lot do) or the last language of the document will remain active

We also write a command to change the current language in the auxiliary files.

```

```

First, check if the user asks for a known language. If so, update the value of $\label{eq:language} \$ and call $\$ riginal TeX to bring $\$ TeX in a certain pre-defined state.

The name of the language is stored in the control sequence \languagename. Then we have to redefine \originalTeX to compensate for the things that have been activated. To save memory space for the macro definition of \originalTeX, we construct the control sequence name for the \noextras $\langle lang \rangle$ command at definition time by expanding the \csname primitive.

Now activate the language-specific definitions. This is done by constructing the names of three macros by concatenating three words with the argument of \selectlanguage, and calling these macros.

The switching of the values of \lefthyphenmin and \righthyphenmin is somewhat different. First we save their current values, then we check if $\langle lang \rangle$ hyphenmins is defined. If it is not, we set default values (2 and 3), otherwise the values in $\langle lang \rangle$ hyphenmins will be used.

otherlanguage

The otherlanguage environment can be used as an alternative to using the \selectlanguage declarative command. When you are typesetting a document which mixes left-to-right and right-to-left typesetting you have to use this environment in order to let things work as you expect them to.

The first thing this environment does is store the name of the language in \languagename; it then calls \selectlanguage_ to switch on everything that is needed for this language The \ignorespaces command is necessary to hide the environment when it is entered in horizontal mode.

```
2047 \long\def\otherlanguage#1{%
2048 \ifnum\bbl@hymapsel=\@cclv\let\bbl@hymapsel\thr@@\fi
2049 \csname selectlanguage \endcsname{#1}%
2050 \iqnorespaces}
```

The \endotherlanguage part of the environment tries to hide itself when it is called in horizontal mode.

```
2051 \long\def\endotherlanguage{%
2052 \global\@ignoretrue\ignorespaces}
```

otherlanguage*

The otherlanguage environment is meant to be used when a large part of text from a different language needs to be typeset, but without changing the translation of words such as 'figure'. This environment makes use of \foreign@language.

```
2053 \expandafter\def\csname otherlanguage*\endcsname#1{%
2054 \ifnum\bbl@hymapsel=\@cclv\chardef\bbl@hymapsel4\relax\fi
2055 \foreign@language{#1}}
```

At the end of the environment we need to switch off the extra definitions. The grouping mechanism of the environment will take care of resetting the correct hyphenation rules and "extras".

2056\expandafter\let\csname endotherlanguage*\endcsname\relax

\foreignlanguage

The \foreignlanguage command is another substitute for the \selectlanguage command. This command takes two arguments, the first argument is the name of the language to use for typesetting the text specified in the second argument. Unlike \selectlanguage this command doesn't switch everything, it only switches the hyphenation rules and the extra definitions for the language specified. It does this within a group and assumes the \extras\lang\rangle command doesn't make any \global changes. The coding is very similar to part of \selectlanguage.

```
2057 \edef\foreignlanguage{%
2058 \noexpand\protect
2059 \expandafter\noexpand\csname foreignlanguage \endcsname}
2060 \expandafter\def\csname foreignlanguage \endcsname#1#2{%
2061 \begingroup
2062 \foreign@language{#1}%
2063 #2%
2064 \endgroup}
```

\foreign@language

This macro does the work for \foreignlanguage and the otherlanguage* environment. First we need to store the name of the language and check that it is a known language. Then it just calls bbl@switch.

```
2065 \def\foreign@language#1{%
      \edef\languagename{#1}%
      \bbl@fixname\languagename
2067
      \bbl@iflanguage\languagename{%

2074
2075
       \let\bbl@select@type\@ne
        \expandafter\bbl@switch\expandafter{\languagename}}}
2076
```

\bbl@patterns

This macro selects the hyphenation patterns by changing the \language register. If special hyphenation patterns are available specifically for the current font encoding, use them instead of the default.

It also sets hyphenation exceptions, but only once, because they are global (here language \lccode's has been set, too). \bbl@hyphenation@ is set to relax until the very first \babelhyphenation, so do nothing with this value. If the exceptions for a language (by its number, not its name, so that :ENC is taken into account) has been set, then use \hyphenation with both global and language exceptions and empty the latter to mark they must not be set again.

```

2114
         \csname\languagename hyphenmins\endcsname\relax
2115
       \fi}}
2116 \let\endhyphenrules\@empty
```

\providehyphenmins

The macro \providehyphenmins should be used in the language definition files to provide a default setting for the hyphenation parameters \lefthyphenmin and \righthyphenmin. If the macro $\langle lang \rangle$ hyphenmins is already defined this command has no effect.

```
2117 \def\providehyphenmins#1#2{%
     \expandafter\ifx\csname #1hyphenmins\endcsname\relax
       \@namedef{#1hyphenmins}{#2}%
2119
2120
     \fi}
```

\set@hyphenmins This macro sets the values of \lefthyphenmin and \righthyphenmin. It expects two values as its argument.

2121 \def\set@hyphenmins#1#2{\lefthyphenmin#1\relax\righthyphenmin#2\relax}

\ProvidesLanguage

The identification code for each file is something that was introduced in $\mathbb{A}T_{\mathsf{F}}X \, 2_{\mathcal{F}}$. When the command \ProvidesFile does not exist, a dummy definition is provided temporarily. For use in the language definition file the command \ProvidesLanguage is defined by babel.

Depending on the format, ie, on if the former is defined, we use a similar definition or not.

```
2122 \ifx\ProvidesFile\@undefined
                                \def\ProvidesLanguage#1[#2 #3 #4]{%
                                            \wlog{Language: #1 #4 #3 <#2>}%

\LdfInit This macro is defined in two versions. The first version is to be part of the 'kernel' of babel, ie. the part that is loaded in the format; the second version is defined in babel.def. The version in the format just checks the category code of the ampersand and then loads babel.def.

> The category code of the ampersand is restored and the macro calls itself again with the new definition from babel.def

```
2138 \def\LdfInit{%
2139 \chardef\atcatcode=\catcode'\@
2140 \catcode'\@=11\relax
2141 \input babel.def\relax
2142 \catcode'\@=\atcatcode \let\atcatcode\relax
2143 \LdfInit}
```

\originalTeX The macro\originalTeX should be known to T_EX at this moment. As it has to be expandable we \let it to \@empty instead of \relax.

```
2144 \ifx\originalTeX\@undefined\let\originalTeX\@empty\fi
```

Because this part of the code can be included in a format, we make sure that the macro which initialises the save mechanism, \babel@beginsave, is not considered to be undefined.

2145 \ifx\babel@beginsave\@undefined\let\babel@beginsave\relax\fi

10.2 Errors

\@nolanerr \@nopatterns The babel package will signal an error when a documents tries to select a language that hasn't been defined earlier. When a user selects a language for which no hyphenation patterns were loaded into the format he will be given a warning about that fact. We revert to the patterns for \language=0 in that case. In most formats that will be (US)english, but it might also be empty.

\@noopterr

When the package was loaded without options not everything will work as expected. An error message is issued in that case.

When the format knows about \PackageError it must be $L^{AT}EX 2_{\varepsilon}$, so we can safely use its error handling interface. Otherwise we'll have to 'keep it simple'.

```

11 Loading hyphenation patterns

The following code is meant to be read by iniT_EX because it should instruct T_EX to read hyphenation patterns. To this end the docstrip option patterns can be used to include this code in the file hyphen.cfg. Code is written with lower level macros.

toks8 stores info to be shown when the program is run.

We want to add a message to the message IATEX 2.09 puts in the \everyjob register. This could be done by the following code:

```
% \let\orgeveryjob\everyjob
% \def\everyjob#1{%
% \orgeveryjob{#1}%
% \orgeveryjob\expandafter{\the\orgeveryjob\immediate\write16{%
% hyphenation patterns for \the\loaded@patterns loaded.}}%
% \let\everyjob\orgeveryjob\let\orgeveryjob\@undefined}
%
```

The code above redefines the control sequence \everyjob in order to be able to add something to the current contents of the register. This is necessary because the processing of hyphenation patterns happens long before \LaTeX fills the register. There are some problems with this approach though.

• When someone wants to use several hyphenation patterns with SIJTEX the above scheme won't work. The reason is that SIJTEX overwrites the contents of the \everyjob register with its own message.

 Plain T_FX does not use the \everyjob register so the message would not be displayed.

To circumvent this a 'dirty trick' can be used. As this code is only processed when creating a new format file there is one command that is sure to be used, \dump. Therefore the original \dump is saved in \org@dump and a new definition is

To make sure that LATEX 2.09 executes the \@begindocumenthook we would want to alter \begin{document}, but as this done too often already, we add the new code at the front of \@preamblecmds. But we can only do that after it has been defined, so we add this piece of code to \dump.

This new definition starts by adding an instruction to write a message on the terminal and in the transcript file to inform the user of the preloaded hyphenation patterns.

Then everything is restored to the old situation and the format is dumped.

       \process@language{#1#2}{#3}{#4}%
2222
     \fi
2223
     \ignorespaces}
2224
```

\process@synonym This macro takes care of the lines which start with an =. It needs an empty token register to begin with. \bbl@languages is also set to empty.

```
2225 \toks@{}
2226 \def\bbl@languages{}
```

When no languages have been loaded yet, the name following the = will be a synonym for hyphenation register 0. So, it is stored in a token register and executed when the first pattern file has been processed. (The \relax just helps to the \if below catching synonyms without a language.)

Otherwise the name will be a synonym for the language loaded last. We also need to copy the hyphenmin parameters for the synonym.

```
2227 \def\process@synonym#1{%

2236
2237
      \fi}
```

\process@language

The macro \process@language is used to process a non-empty line from the 'configuration file'. It has three arguments, each delimited by white space. The first argument is the 'name' of a language; the second is the name of the file that contains the patterns. The optional third argument is the name of a file containing hyphenation exceptions.

The first thing to do is call \addlanguage to allocate a pattern register and to make that register 'active'. Then the 'name' of the language that will be loaded now is added to the token register \toks8. and finally the pattern file is read. For some hyphenation patterns it is needed to load them with a specific font encoding selected. This can be specified in the file language.dat by adding for instance ':T1' to the name of the language. The macro \bbl@get@enc extracts the font encoding from the language name and stores it in \bbl@hyph@enc. The latter can be used in hyphenation files if you need to set a behaviour depending on the given encoding (it is set to empty if no encoding is given).

Pattern files may contain assignments to \lefthyphenmin and \righthyphenmin. T_EX does not keep track of these assignments. Therefore we try to detect such assignments and store them in the $\langle lang \rangle$ hyphenmins macro. When no assignments were made we provide a default setting.

Some pattern files contain changes to the \lccode en \uccode arrays. Such changes should remain local to the language; therefore we process the pattern file in a group; the \patterns command acts globally so its effect will be remembered. Then we globally store the settings of \lefthyphenmin and \righthyphenmin and close the group.

When the hyphenation patterns have been processed we need to see if a file with hyphenation exceptions needs to be read. This is the case when the third argument is not empty and when it does not contain a space token. (Note however there is no need to save hyphenation exceptions into the format.)

\bbl@languages saves a snapshot of the loaded languagues in the form \bbl@elt{ $\langle language-name \rangle$ }{ $\langle number \rangle$ } { $\langle patterns-file \rangle$ }{ $\langle exceptions-file \rangle$ }. Note the last 2 arguments are empty in 'dialects' defined in language.dat with =. Note also the language name can have encoding info.

Finally, if the counter \language is equal to zero we execute the synonyms stored.

```

\readconfigfile The configuration file can now be opened for reading.

```
2298 \openin1 = language.dat
```

See if the file exists, if not, use the default hyphenation file hyphen.tex. The user will be informed about this.

Pattern registers are allocated using count register \last@language. Its initial value is 0. The definition of the macro \newlanguage is such that it first increments the count register and then defines the language. In order to have the first patterns loaded in pattern register number 0 we initialize \last@language with the value -1.

```
2306 \last@language\m@ne
```

We now read lines from the file until the end is found

```
2307 \loop
```

While reading from the input, it is useful to switch off recognition of the end-of-line character. This saves us stripping off spaces from the contents of the control sequence.

```
2308 \endlinechar\m@ne
2309 \read1 to \bbl@line
2310 \endlinechar'\^M
```

If the file has reached its end, exit from the loop here. If not, empty lines are skipped. Add 3 space characters to the end of \bbl@line. This is needed to be able to recognize the arguments of \process@line later on. The default language should be the very first one.

```
2311 \if T\ifeof1F\fi T\relax
2312 \ifx\bbl@line\@empty\else
2313 \edef\bbl@line\space\space\space\%
2314 \expandafter\process@line\bbl@line\relax
2315 \fi
2316 \repeat
```

Check for the end of the file. We must reverse the test for \ifeof without \else. Then reactivate the default patterns,

```
2317 \begingroup
2318 \def\bbl@elt#1#2#3#4{%
2319 \global\language=#2\relax
2320 \gdef\languagename{#1}%

2351 \(/patterns\)
```

Here the code for iniT_FX ends.

12 The 'nil' language

This 'language' does nothing, except setting the hyphenation patterns to nohyphenation.

For this language currently no special definitions are needed or available. The macro \LdfInit takes care of preventing that this file is loaded more than once, checking the category code of the @ sign, etc.

```
2352 \langle *nil \rangle
2353 \ProvidesLanguage{nil}[\langle \langle date \rangle \rangle \langle \langle version \rangle \rangle Nil language]
2354 \LdfInit{nil}{datenil}
```

When this file is read as an option, i.e. by the \usepackage command, nil could be an 'unknown' language in which case we have to make it known.

```
2355 \ifx\l@nohyphenation\@undefined
2356 \@nopatterns{nil}
2357 \adddialect\l@nil0
2358 \else
2359 \let\l@nil\l@nohyphenation
```

2360 \fi

This macro is used to store the values of the hyphenation parameters \lefthyphenmin and \righthyphenmin.

```
2361 \providehyphenmins{\CurrentOption}{\m@ne\m@ne}
```

The next step consists of defining commands to switch to (and from) the 'nil' language.

\captionnil

```
\label{eq:captionsnil} $$ \addenil $_{2362} \le \addenil @empty $$ $_{2363} \le \addenil @empty $$ $$
```

The macro \ldf@finish takes care of looking for a configuration file, setting the main language to be switched on at \begin{document} and resetting the category code of @ to its original value.

```
2364 \ldf@finish{nil}
2365 ⟨/nil⟩
```

13 Support for Plain T_EX

13.1 Not renaming hyphen.tex

As Don Knuth has declared that the filename hyphen.tex may only be used to designate *his* version of the american English hyphenation patterns, a new solution has to be found in order to be able to load hyphenation patterns for other languages in a plain-based T_FX-format. When asked he responded:

That file name is "sacred", and if anybody changes it they will cause severe upward/downward compatibility headaches.

People can have a file localhyphen.tex or whatever they like, but they mustn't diddle with hyphen.tex (or plain.tex except to preload additional fonts).

The files bplain.tex and blplain.tex can be used as replacement wrappers around plain.tex and lplain.tex to acheive the desired effect, based on the babel package. If you load each of them with $\operatorname{ini} T_E X$, you will get a file called either bplain.fmt or blplain.fmt, which you can use as replacements for plain.fmt and lplain.fmt.

As these files are going to be read as the first thing $iniT_EX$ sees, we need to set some category codes just to be able to change the definition of $\inv Input$

```
2366 \*bplain | blplain \\
2367 \catcode'\{=1 % left brace is begin-group character
2368 \catcode'\}=2 % right brace is end-group character
2369 \catcode'\#=6 % hash mark is macro parameter character
```

Now let's see if a file called hyphen.cfg can be found somewhere on $T_E X$'s input path by trying to open it for reading...

```
2370 \openin 0 hyphen.cfg
```

If the file wasn't found the following test turns out true.

```
2371 \ifeof0
2372 \else
```

When hyphen.cfg could be opened we make sure that *it* will be read instead of the file hyphen.tex which should (according to Don Knuth's ruling) contain the american English hyphenation patterns and nothing else.

We do this by first saving the original meaning of \input (and I use a one letter control sequence for that so as not to waste multi-letter control sequence on this in the format).

```
2373 \let\a\input
```

Then \input is defined to forget about its argument and load hyphen.cfg instead.

```
2374 \def\input #1 {%
2375 \let\input\a
2376 \a hyphen.cfg
```

Once that's done the original meaning of \input can be restored and the definition of \a can be forgotten.

```
2377 \let\a\undefined
2378 }
2379 \fi
2380 \langle /bplain \left blplain \rangle
```

Now that we have made sure that hyphen.cfg will be loaded at the right moment it is time to load plain.tex.

```
2381 ⟨bplain⟩\a plain.tex 2382 ⟨blplain⟩\a lplain.tex
```

Finally we change the contents of \fmtname to indicate that this is *not* the plain format, but a format based on plain with the babel package preloaded.

```
2383 \def\fmtname{babel-plain}
2384 \def\fmtname{babel-lplain}
```

When you are using a different format, based on plain.tex you can make a copy of blplain.tex, rename it and replace plain.tex with the name of your format file.

13.2 Emulating some LATEX features

The following code duplicates or emulates parts of \LaTeX 2 ε that are needed for babel.

We need to define \localcfg for plain users as the LATEX definition uses \localcfg for plain users as the LATEX definition uses \localcfg for plain users as the LATEX definition uses

```

The following control sequences are used in babel. def but are not defined for plain $T_E X$.

```
2717 \DeclareTextSymbol{\textquotedblleft} \{0T1\} \{92\} 2718 \DeclareTextSymbol{\textquotedblright} \{0T1\} \{'\"\} 2719 \DeclareTextSymbol{\textquoteleft} \{0T1\} \{'\'\} 2720 \DeclareTextSymbol{\textquoteright} \{0T1\} \{'\'\} 2721 \DeclareTextSymbol{\\i}\{0T1\} \{16\} 2722 \DeclareTextSymbol{\\ss}\{0T1\} \{25\}
```

For a couple of languages we need the \LaTeX control sequence \scriptsize to be available. Because plain \Tau EX doesn't have such a sofisticated font mechanism as \LaTeX has, we just \let it to \sevenrm.

```
2723\ifx\scriptsize\@undefined
2724 \let\scriptsize\sevenrm
2725\fi
```

13.5 Babel options

The file babel.def expects some definitions made in the \LaTeX style file. So we must provide them at least some predefined values as well some tools to set them (even if not all options are available). There in no package options, and therefore and alternative mechanism is provided. For the moment, only

\babeloptionstrings and \babeloptionmath are provided, which can be defined before loading babel. \BabelModifiers can be set too (but not sure it works).

```

14 Tentative font handling

A general solution is far from trivial:

- \addfontfeature only sets it for the current family and it's not very efficient, and
- \defaultfontfeatures requires to redefine the font (and the options aren't "orthogonal").

```

15 Hooks for XeTeX and LuaTeX

15.1 **XeTeX**

Unfortunately, the current encoding cannot be retrieved and therefore it is reset always to utf8, which seems a sensible default.

 \LaTeX sets many "codes" just before loading hyphen.cfg. That is not a problem in luatex, but in xetex they must be reset to the proper value. Most of the work is done in xe(la)tex.ini, so here we just "undo" some of the changes done by \LaTeX Anyway, for consistency LuaT_FX also resets the catcodes.

```
2778 \langle \langle *Restore Unicode catcodes before loading patterns \rangle \rangle \equiv
      \begingroup

16 Conclusion

A system of document options has been presented that enable the user of LATEX to adapt the standard document classes of LATEX to the language he or she prefers to use. These options offer the possibility of switching between languages in one document. The basic interface consists of using one option, which is the same for *all* standard document classes.

In some cases the language definition files provide macros that can be useful to plain T_EX users as well as to IAT_EX users. The babel system has been implemented so that it can be used by both groups of users.

17 Acknowledgements

I would like to thank all who volunteered as β -testers for their time. I would like to mention Julio Sanchez who supplied the option file for the Spanish language and Maurizio Codogno who supplied the option file for the Italian language. Michel Goossens supplied contributions for most of the other languages. Nico Poppelier helped polish the text of the documentation and supplied parts of the macros for the Dutch language. Paul Wackers and Werenfried Spit helped find and repair bugs.

During the further development of the babel system I received much help from Bernd Raichle, for which I am grateful.
